The NASA STI Office ... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Office plays a key part in helping NASA maintain this important role.

The NASA STI Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Office is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the Office's diverse offerings include creating custom thesauri, translating material to or from 34 foreign languages, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Office, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

NASA Access Help Desk

Scientific and Technical Aerospace Reports

STAR

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Office.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
    - Subject
    - Personal author
    - Corporate source
    - Contract number
    - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Office, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON.

The NASA STI Office gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Office, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **2117**

02 AERODYNAMICS **2120**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **2125**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **2126**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **2128**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **2138**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **2139**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **2141**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **2142**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) **2144**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS **2146**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) **2154**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **2154**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **2159**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING **2161**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE 2161
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION .... N.A.
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER 2166
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) 2177

24 COMPOSITE MATERIALS 2179
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY 2199
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS 2211
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS 2224
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS 2242
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING 2244
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) 2245
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR 2247
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING 2259
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER 2273
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY 2289
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS 2294
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING 2300
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY 2306
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS 2307
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) 2313

43 EARTH RESOURCES AND REMOTE SENSING 2313
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION 2316
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION 2326
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS 2334
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY 2340
Includes weather forecasting and modification.

48 OCEANOGRAPHY 2345
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) 2348

52 AEROSPACE MEDICINE 2352
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES 2355
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT 2358
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY .... N.A.
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) .... N.A.

60 COMPUTER OPERATIONS AND HARDWARE 2361
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE 2362
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS 2376
Includes computer networks and special application computer systems.

63 CYBERNETICS 2379
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS 2388
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY 2393
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS 2396
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS 2396
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

70 PHYSICS (GENERAL) 2398
For precision time and time interval (PTTI) see *35 Instrumentation and Photography*; for geophysics, astrophysics or solar physics see *46 Geophysics, 90 Astrophysics*, or *92 Solar Physics.*

71 ACOUSTICS 2400
Includes sound generation, transmission, and attenuation. For noise pollution see *45 Environment Pollution.*

72 ATOMIC AND MOLECULAR PHYSICS 2403
Includes atomic structure, electron properties, and molecular spectra.

73 NUCLEAR AND HIGH-ENERGY PHYSICS 2419
Includes elementary and nuclear particles; and reactor theory. For space radiation see *93 Space Radiation.*

74 OPTICS 2423
Includes light phenomena and optical devices. For lasers see *36 Lasers and Masers.*

75 PLASMA PHYSICS 2429
Includes magnetohydrodynamics and plasma fusion. For ionospheric plasmas see *46 Geophysics.* For space plasmas see *90 Astrophysics.*

76 SOLID-STATE PHYSICS 2436
Includes superconductivity. For related information see also *33 Electronics and Electrical Engineering* and *36 Lasers and Masers.*

77 THERMODYNAMICS AND STATISTICAL PHYSICS 2447
Includes quantum mechanics; theoretical physics; and Bose and Fermi statistics. For related information see also *25 Inorganic and Physical Chemistry* and *34 Fluid Mechanics and Heat Transfer.*

SOCIAL SCIENCES

80 SOCIAL SCIENCES (GENERAL) 2450
Includes educational matters.

81 ADMINISTRATION AND MANAGEMENT 2450
Includes management planning and research.

82 DOCUMENTATION AND INFORMATION SCIENCE 2452
Includes information management; information storage and retrieval technology; technical writing; graphic arts; and micrography. For computer documentation see *61 Computer Programming and Software.*

83 ECONOMICS AND COST ANALYSIS .... N.A.
Includes cost effectiveness studies.

84 LAW, POLITICAL SCIENCE AND SPACE POLICY .... N.A.
Includes NASA appropriation hearings; aviation law; space law and policy; international law; international cooperation; and patent policy.

85 URBAN TECHNOLOGY AND TRANSPORTATION 2458
Includes applications of space technology to urban problems; technology transfer; technology assessment; and surface and mass transportation. For related information see *03 Air Transportation and Safety, 16 Space Transportation,* and *44 Energy Production and Conversion.*

SPACE SCIENCES For related information see also *Geosciences.*

88 SPACE SCIENCES (GENERAL) .... N.A.

89 ASTRONOMY 2458
Includes radio, gamma-ray, and infrared astronomy; and astrometry.

90 ASTROPHYSICS 2461
Includes cosmology; celestial mechanics; space plasmas; and interstellar and interplanetary gases and dust. For related information see also *75 Plasma Physics.*

91 LUNAR AND PLANETARY EXPLORATION 2463
Includes planetology; and manned and unmanned flights. For spacecraft design or space stations see *18 Spacecraft Design, Testing and Performance.*

92 SOLAR PHYSICS 2464
Includes solar activity, solar flares, solar radiation and sunspots. For related information see also *93 Space Radiation.*

93 SPACE RADIATION 2465
Includes cosmic radiation; and inner and outer earth's radiation belts. For biological effects of radiation see *52 Aerospace Medicine.* For theory see *73 Nuclear and High-Energy Physics.*

GENERAL

Includes aeronautical, astronautical, and space science related histories, biographies, and pertinent reports too broad for categorization; histories or broad overviews of NASA programs.

The effects of a forward-swept front rotor on the flowfield of a counterrotation model propeller at takeoff conditions at zero degree angle of attack are studied by solving the unsteady three-dimensional Euler equations. The configuration considered is an uneven blade count counterrotation model with twelve forward-swept blades on the fore rotor and ten aft-swept blades on the aft rotor. The flowfield is compared with that of a reference aft-swept counterrotation geometry and Laser Doppler Velocimeter (LDV) measurements. At the operating conditions considered, the forward-swept blade experiences a higher tip loading and produces a stronger tip vortex compared to the aft-swept blade, consistent with the LDV and acoustic measurements. Neither the solution nor the LDV data indicated the formation of a leading edge vortex. The predicted radial distribution of the circumferentially averaged axial velocity at the measurement station agreed very closely with LDV data, while crossflow velocities showed poor agreement. The discrepancy between prediction and LDV data of tangential and radial velocities is due in part to the insufficient mesh resolution in the region between the rotors and in the tip region to track the tip vortex. The vortex is diffused by the time it arrives at the measurement station. The uneven blade count configuration requires the solution to be carried out for six blade passages of the fore rotor and five passages of the aft rotor, thus making grid refinement prohibitive.

WINCLR: A COMPUTER CODE FOR HEAT TRANSFER AND CLEARANCE CALCULATION IN A COMPRESSOR
T. K. Bose and S. N. B. Murthy Jun. 1994 170 p
(Contract NAG3-481; RTOP 505-62-52; DTFA03-83-A-00328)
(NASA-CR-195436; E-9461; NAS 1.26:195436; DOT/FAA/CT-TN94-61; M/NAFA/94-1) Avail: CASI HC A08/MF A02

One of the concerns during inclement weather operation of aircraft in rain and hail storm conditions is the nature and extent of changes in compressor casing clearance. An increase in clearance affects efficiency while a decrease may cause blade rubbing with the casing. The change in clearance is the result of geometrical dimensional changes in the blades, the casing and the rotor due to heat transfer between those parts and the two-phase working fluid. The heat transfer interacts nonlinearly with the performance of the compressor, and, therefore, the determination of clearance changes necessitates a simultaneous determination of change in performance of the compressor. A computer code the WINCLR has been designed for the determination of casing clearance, that is operated interactively with the PURDU-WINCOF I code designed previously for determining the performance of a compressor. A detailed description of the WINCLR code is provided in a companion report. The current report provides details of the code with an illustrative example of application to the case of a multistage compressor. It is found in the example case that under given ingestion and operational conditions, it is possible for a compressor to undergo changes in performance in the front stages and rubbing in the back stages. FLUTTER CLEARANCE FLIGHT TESTS OF AN OV-10A AIRPLANE MODIFIED FOR WAKE VORTEX FLIGHT EXPERIMENTS
Robert V. Doggett, Jr., Jose A. Rivera, Jr., and Eric C. Stewart Apr. 1995 14 p
(RTOP 505-63-50-13)
(NASA-TM-109168; NAS 1.15:109168) Avail: CASI HC A03/MF A01

The envelope expansion, flight flutter tests of a modified OV-10A aircraft are described. For the wake vortex research program, the airplane was modified to incorporate three forward-extending instrumentation booms, one extending forward from each wing tip and one from the right side of the fuselage. The booms were instrumented with sensors to measure the velocity and direction of local air flow. The flutter test results show that the modified OV-10A aircraft is free from flutter at speeds up to 330 KEAS at 5000 feet altitude. Author

STRATEGY IN THE COMMERCIAL AIRCRAFT INDUSTRY IN THE UNITED STATES: A COMPARISON OF DECISIONMAKING BY MCDONNELL-DOUGLAS AND BOEING AIRCRAFT COMPANIES FROM 1977-1983 Research Report, Aug. 1993 - Apr. 1994
Dave Gillett Apr. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288289; NDU-ICAF-94-F2) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper studies strategic decision making in the commercial aircraft manufacturing market. It compares the decisions made by McDonnell-Douglas Corporation with those of Boeing Aircraft Company in the late 70s and early 80s. The study concludes that strategic decisions were made based on each companies vision of its core business. McDonnell-Douglas refused to risk its capital on a new commercial aircraft because its core business was defense. Boeing on the other hand was willing to risk the company on new aircraft development because its core business was the commercial aircraft market. DTIC

N95-26455 Industrial Coll. of the Armed Forces, Washington, DC.
SURVIVING THE PEACE. LESSONS LEARNED FROM THE AIRCRAFT INDUSTRY IN THE 1920S AND 1930S Research Report, Aug. 1993 - Apr. 1994
Ellen M. Pawlikowski Apr. 1994 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288284; NDU-ICAF-94-F56) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Many of America's defense industries are struggling to survive in today's peacetime environment. As they prepare for the future, US business and government leaders can learn from defense industries that survived the last extended peace. This paper examines the American aircraft industry during the peace from 1920 to 1939. During that time, the industry retained core capability for future defense needs while establishing alternative markets for its products. They succeeded because they placed a strong emphasis on broad based R&D and conducted a concerted effort to establish alternative markets. Industry and national leaders used those alternative markets to strengthen the industry and the national economy. The federal government supported industry efforts by funding research and development, establishing a national aviation infrastructure, and opening foreign markets. The Congress also funded military aircraft production that helped the industry weather market downturns. Although commercial markets existed, aircraft manufacturers failed to achieve independence from government contracts. This failure was due to government procurement practices, poor business management by aviation pioneers, the high cost of technology development, and the small size of commercial markets. Today's defense industries should study the lessons of the aircraft manufacturers as they determine business strategy for the 1990s. The federal government can also apply these lessons as it makes decisions regarding research investments, military-commercial integration, acquisition reform, and export policies. We can never repeat history, but we can learn from it. By studying the lessons of the last extended peace, perhaps we can avoid the mistakes and duplicate the successes. DTIC

DEVELOPMENT OF REPAIR PROCESSES AND SOURCES FOR C/KC-135 AIRCRAFT WINDOWS/WINDSHIELDS Final Technical Report, 1 Sep. 1991 - 31 Jan. 1994
Richard J. Olson Sep. 1994 521 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F09603-90-D-2217)
(AD-A288348) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The U.S. Air Force has historically rejected the notion of using repaired windows/windshields (W/WS). With increasing pressure to reduce fleet operating costs and based on the favorable experience that commercial fleets have had, interest in using repaired W/WS is receiving greater attention. To ensure that repaired W/WS are safe and that they provide similar benefits for the Air Force, a program of evaluation and testing was undertaken to compare new and repaired C/KC-135 W/WS. Optical and electrical properties, pressure integrity, and bird impact resistance of repaired and new W/WS have been evaluated. The bird impact test results are the first data that the Air Force have collected for C/KC-135 W/WS. The functional testing indicated that repaired W/WS are not equal to new W/WS; the new W/WS outperform the repaired W/WS. However, in terms of removal for cause criteria and absolute performance requirements, the repaired W/WS appear to be good enough. Concerning costs, the direct costs for repair of the W/WS in this program ranged from 65-75% of new W/WS cost, suggesting that money can be saved. DTIC

DEVELOPMENT AND VALIDATION OF A BLADE-ELEMENT MATHEMATICAL MODEL FOR THE AH-64A APACHE HELICOPTER
M. Hossein Mansur Apr. 1995 98 p
(RTOP 505-59-36)
(NASA-TM-108863; A-95034; NAS 1.15:108863; USAATCOM-TR-94-A-022)
Avail: CASI HC A05/MF A02

A high-fidelity blade-element mathematical model for the AH-64A Apache Advanced Attack Helicopter has been developed by the Aeroflightdynamics Directorate of the U.S. Army's Aviation and Troop Command (ATCOM) at Ames Research Center. The model is based on the McDonnell Douglas Helicopter Systems' (MDHS) Fly Real Time (FLYRT) model of the AH-64A (acquired under contract) which was modified in-house and augmented with a blade-element-type main-rotor module. This report describes, in detail, the development of the rotor module, and presents some results of an extensive validation effort. Author

ASIAN AERONAUTICS: TECHNOLOGY ACQUISITION DRIVES INDUSTRY DEVELOPMENT. REPORT TO CONGRESSIONAL REQUESTERS
4 May 1994 19 p
(GAO/NSIAD-94-140; B-256707) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20884-6015 HC

This report responds to a request to review the aeronautics research and development (R&D) activities of Asian countries. More specifically, we are providing information on (1) the approaches these Asian nations use to develop their aeronautics industries, (2) the level of aeronautics development each country has achieved, and (3) the implications of this development for the U.S. aeronautics industry. This report represents an amalgamation of many pieces of data obtained from dozens of U.S. and foreign sources. However, because of the nature of much of the data, we were unable to verify its accuracy or make an independent assessment of the extent and progress of each country's R&D efforts. (NIAR-94-1) Avail: CASI HC A12/MF A03

A wide range of topics concerned with aerodynamics and design considerations is addressed. Also addressed are structures-related topics and the manufacturing considerations associated with the designing of a high altitude long endurance aircraft. The airspace database is discussed, as well as the results and capabilities of a new jet facility at the University of Kansas. As part of miscellaneous topics, prevention and control of inlet unstart using an SR-71 simulation is presented, along with an easy way to analyze longitudinal and lateral-directional trim problems with AEO or OEI. For individual titles, see N95-26942 through N95-26956.

PRELIMINARY DESIGN PROBLEMS AND SOLUTIONS FOR A SUPERSONIC OBLIQUE ALL-WING TRANSPORT AIRCRAFT Abstract only c05
Troy Downen *In* Wichita State Univ., AIAA Techfest 20 Proceedings 1994 2 p (For primary document see N95-26941 09-01)
Avail: CASI HC A01/MF A03

Although the oblique all-wing transport (OAWT) has been studied in some detail for the last twenty years, some of the most basic design features of such aircraft have not received much attention. Due to the unique configuration of the OAWT, passenger ingress/egress and cargo loading will present problems, as will the internal cabin arrangement, engine placement and take-off attitude. This presentation examines the nature of these preliminary design problems and proposes one or more viable solutions for each. Author

THE HIGH SPEED CIVIL TRANSPORT AND NASA'S HIGH SPEED RESEARCH (HSR) PROGRAM Abstract only c05
Robert J. Shaw *In* Wichita State Univ., AIAA Techfest 20 Proceedings 1994 2 p (For primary document see N95-26941 09-01)
Avail: CASI HC A01/MF A03

Ongoing studies being conducted not only in this country but in Europe and Asia suggest that a second generation supersonic transport, or High-Speed Civil Transport (HSCT), could become an important part of the 21st century international air transportation system. However, major environmental compatibility and economic viability issues must be resolved if the HSCT is to become a reality. This talk will overview the NASA High-Speed Research (HSR) program which is aimed at providing the U.S. industry with a technology base to allow them to consider launching an HSCT program early in the next century. The talk will also discuss some of the comparable activities going on within Europe and Japan. Author

Avail: CASI HC A01/MF A03

There is a current need for a low cost, low maintenance, unmanned High Altitude Long Endurance (HALE) aircraft to conduct high altitude atmospheric studies. Future military applications are possible. The preliminary design of a HALE vehicle is presented with special attention to low cost (low maintenance, low support requirements) and manufacturability. Emphasis is also placed on the propulsion system design, using an advanced ducted engine for low noise and improved propulsive efficiency. Author

AN EASY WAY TO ANALYZE LONGITUDINAL AND LATERAL-DIRECTIONAL TRIM PROBLEMS WITH AEO OR OEI **c08**
Jan Roskam and William Anemaat (Design, Analysis and Research Corp., Lawrence, KS.) *In* Wichita State Univ., AIAA Techfest 20 Proceedings 1994 22 p (For primary document see N95-26941 09-01)
Avail: CASI HC A03/MF A03

Analyzing longitudinal and lateral-directional trim problems of airplanes with all-engines-operating (AEO) and with one-engine-inoperative (OEI) requires the solution of two sets of simultaneous equations. For longitudinal trim the set includes drag, lift, pitching moment, and elevator wheel force equations. For lateral-directional trim the set includes side-force, rolling moment, yawing moment, rudder pedal force, and aileron wheel force equations. Both sets of equations are non-linear; the process of finding a solution is therefore an iterative process. Solutions are very much dependent on the detailed aerodynamic design of the airplane, on the center of gravity location, and on various characteristics of the flight control system. The equations have been programmed as part of the user-friendly Advanced Aircraft Analysis (AAA) program. The purpose of the paper is to discuss several examples of how the stability and control engineer can use this aspect of the AAA program to rapidly resolve issues of control force levels, control force gradients, and flight path stability with AEO and OEI. THE AEROSPACE DATABASE: AN INTRODUCTION TO AIAA'S COMPUTERIZED SOURCE FOR IDENTIFYING SCIENTIFIC AND TECHNICAL INFORMATION Abstract Only **c82**
Thomas G. DePetro *In its* AIAA Techfest 20 Proceedings 1994 2 p (For primary document see N95-26941 09-01)
Avail: CASI HC A01/MF A03

The AIAA Technical Information Service in New York in conjunction with DIALOG Information Services, Inc. in Palo Alto, California provides online and CD-ROM computer access to AIAA's Aerospace Database. This database references scientific and technical literature and information including such sources as NASA documents, reports, and publications, AIAA books, journals papers, and conferences and other relevant items that record the results of aerospace research and development. Beginning with the year 1962 and continuing to the present, the database electronically combines two printed indexes: NASA's 'Scientific and Technical Aerospace Reports' (STAR) and AIAA's 'International Aerospace Abstracts' (IAA). Items written by AIAA members and others can be quickly identified by title, subject descriptors for the 'NASA Thesaurus', keywords, conference, etc. using DIALOG commands and Boolean logic to combine sets of terms in the database. These items are then accessed in libraries, or photocopies can be ordered from the AIAA Quality Express Document delivery service. This session will include a demonstration of the database to show how it can be used in the process of aerospace research and development and technology transfer. Author

PRELIMINARY RESULTS AND RESEARCH CAPABILITIES OF A NEW JET FACILITY AT THE UNIVERSITY OF KANSAS **c09**
Jason Frank, Tom Sherwood, and Ray Taghavi *In* Wichita State Univ., AIAA Techfest 20 Proceedings 1994 16 p (For primary document see N95-26941 09-01)
Avail: CASI HC A03/MF A03

The recently completed free jet facility at the University of Kansas was designed to be versatile in research capabilities. The free-shear flow testing apparatus operates in both subsonic and supersonic regimes to test jet exhaust nozzles, diffusers, and combustor geometries with and without swirl. Currently proposed areas of research have application in engine exhaust design, jet diffusion, and supersonic jet noise research. The equipment is comprised of a plenum tank, flow conditioners, bellmouth, and adapter and various subsonic and supersonic nozzle attachments. A jet engine starting unit provides enough flow to choke a 3.5 inch diameter nozzle. Flow field variables can be measured with pitot tubes and hot-wire anemometry, as well as with laser Doppler velocimetry. Preliminary data indicate a top hat exit velocity profile with less than 1% core turbulence intensity. Author

VISUALIZATION OF THE MULTIPLE SUPERSONIC JET OSCILLATIONS BY SWEPT FOCUSED STROBED SCHLIEREN TECHNIQUE
Ganesh Raman and Ray Taghavi (Kansas Univ., Lawrence, KS.) *In* Wichita State Univ., AIAA Techfest 20 Proceedings 1994 8 p (For primary document see N95-26941 09-01)
Avail: CASI HC A02/MF A03

The natural flapping mode oscillations of a multiple rectangular supersonic jet is visualized by the newly developed strobed focusing schlieren technique. Four parallel underexpanded, converging rectangular jets, exhausting into ambient air at a fully expanded Mach number of 1.61 are visualized in this study. This technique clearly shows the oscillations at the natural screech frequency and offers tremendous flexibility in the study of these flow fields. Author

INCORPORATING BIPLANE WING THEORY INTO A LARGE, SUBSONIC, ALL-CARGO TRANSPORT c05
Michael K. Zyskowski *In* Wichita State Univ., AIAA Techfest 20 Proceedings 1994 p 1-15 (For primary document see N95-26941 09-01)
Avail: CASI HC A03/MF A03

If the air-cargo market increases at the pace predicted, a new conceptual aircraft will be demanded to meet the needs of the air-cargo industry. Furthermore, it has been found that not only should this aircraft be optimized to carry the intermodal containers used by the current shipping industry, but it should also be be able to operate at existing airports. The best solution to these problems is a configuration incorporating a bi-wing planform, which has resulted in significant improvements over the monoplane in lift/drag, weight reduction, and span reduction. The future of the air-cargo market, biplane theory, wind tunnel tests, and a comparison of the aerodynamic characteristics of the biplane and monoplane are discussed. The factors pertaining to a biplane cargo transport are then examined, resulting in biplane geometric parameters. Author

PROCEEDINGS OF THE AIAA/FAA JOINT SYMPOSIUM ON GENERAL AVIATION SYSTEMS Final Report
Gus Ferrara and Roberto DiMichele Sep. 1994 627 p Symposium held in Starkville, MS, 24-25 May 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289830; DOT/FAA/CT-94/63) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The 1994 AIAA/FAA Joint Symposium on General Aviation Systems was the result of the combined efforts of the AIAA General Aviation Systems Technical Committee and the Federal Aviation Administration Technical Center. This symposium offered the opportunity to present and review the current state of the art in research that is being conducted in support of general aviation. All told, the papers presented covered the entire spectrum of research, and the participants had the opportunity to hear presentations on everything from alternate fuels to developments in air traffic control. AIRFOIL MODIFICATION EFFECTS ON SUBSONIC AND TRANSONIC PRESSURE DISTRIBUTIONS AND PERFORMANCE FOR THE EA-6B AIRPLANE
Dennis O. Allison and William G. Sewall May 1995 86 p
(RTOP 505-59-10-30)
(NASA-TP-3516; L-17360; NAS 1.60:3516) Avail: CASI HC A05/MF A01

Longitudinal characteristics and wing-section pressure distributions are compared for the EA-6B airplane with and without airfoil modifications. The airfoil modifications were designed to increase low-speed maximum lift for maneuvering, while having a minimal effect on transonic performance. Section contour changes were confined to the leading-edge slat and trailing-edge flap regions of the wing. Experimental data are analyzed from tests in the Langley 16-Foot Transonic Tunnel on the baseline and two modified wing-fuselage configurations with the slats and flaps in their retracted positions. Wing modification effects on subsonic and transonic performance are seen in wing-section pressure distributions of the various configurations at similar lift coefficients. The modified-wing configurations produced maximum lift coefficients which exceeded those of the baseline configuration at low-speed Mach numbers (0.300 and 0.400). This benefit was related to the behavior of the wing upper surface leading-edge suction peak and the behavior of the trailing-edge pressure. At transonic Mach numbers (0.725 to 0.900), the wing modifications produced a somewhat stronger nose-down pitching moment, a slightly higher drag at low-lift levels, and a lower drag at higher lift levels. CFD RESEARCH, PARALLEL COMPUTATION AND AERODYNAMIC OPTIMIZATION Final Report, Jul. 1989 - Jan. 1995
James S. Ryan Jan. 1995 7 p Original contains color illustrations
(Contracts NCC2-505; NCC2-796)
(NASA-CR-197748; NAS 1.26:197748; MCAT-95-18) Avail: CASI HC A02/MF A01; 1 functional color page

Over five years of research in Computational Fluid Dynamics and its applications are covered in this report. Using CFD as an established tool, aerodynamic optimization on parallel architectures is explored. The objective of this work is to provide better tools to vehicle designers. Submarine design requires accurate force and moment calculations in flow with thick boundary layers and large separated vortices. Low noise production is critical, so flow into the propulsor region must be predicted accurately. The High Speed Civil Transport (HSCT) has been the subject of recent work. This vehicle is to be a passenger vehicle with the capability of cutting overseas flight times by more than half. A successful design must surpass the performance of comparable planes. Fuel economy, other operational costs, environmental impact, and range must all be improved substantially. For all these reasons, improved design tools are required, and these tools must eventually integrate optimization, external aerodynamics, propulsion, structures, heat transfer and other disciplines. NUMERICAL INVESTIGATION TO S-INLET FLOWS (NUMERICAL SIMULATION STUDY OF S-INLET FLOWS)
Zhang Shucheng and Huang Xijun 17 Nov. 1994 20 p Transl. into ENGLISH from unidentified Chinese language periodical, p 169-174 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289590; NAIC-ID(RS)T-0922-92) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This work improves Denton's finite volume time marching methods. It takes this type of method, in which there is 1st order accuracy in time and 2d order accuracy in space, and improves it to be a calculation method in which there is 2d degree accuracy in time and 2d degree accuracy in space. In conjunction with this, application is made to numerical simulations of inlet flow fields associated with the interior flows of S type inlets as well as exterior flows which inlets possess. Calculations are carried out for actual cases, and we obtained reasonable calculation results. DTIC

NUMERICAL SIMULATION OF THE FLOW ABOUT THE F-18 HARV AT HIGH ANGLE OF ATTACK Final Report
Scott M. Murman Feb. 1995 36 p Original contains color illustrations
(Contract NCC2-729)
(NASA-CR-197755; NAS 1.26:197755; MCAT-95-13) Avail: CASI HC A03/MF A01; 2 functional color pages

This research has been aimed at validating numerical methods for computing the flow about the complete F-18 HARV at alpha = 30 deg and alpha = 45 deg. At 30 deg angle of attack, the flow about the F-18 is dominated by the formation, and subsequent breakdown, of strong vortices over the wing leading-edge extensions (LEX). As the angle of attack is increased to alpha = 45 deg, the fuselage forebody of the F-18 contains significant laminar and transitional regions which are not present at alpha = 30 deg. Further, the flow over the LEX at alpha = 45 deg is dominated by an unsteady shedding in time, rather than strong coherent vortices. This complex physics, combined with the complex geometry of a full-aircraft configuration, provides a challenge for current computational fluid dynamics (CFD) techniques. The following sections present the numerical method and grid generation scheme that was used, a review of prior research done to numerically model the F-18 HARV, and a discussion of the current research. The current research is broken into three main topics; the effect of engine-inlet mass-flow rate on the F-18 vortex breakdown position, the results using a refined F-18 computational model to compute the flow at alpha = 30 deg and alpha = 45 deg, and research done using the simplified geometry of an ogive-cylinder configuration to investigate the physics of unsteady shear-layer shedding. The last section briefly summarizes the discussion. Derived from text

WIND TUNNEL EXPERIMENTS ON WAKE FLOW FIELD BEHIND A REENTRY CAPSULE FROM A VIEWPOINT OF PARACHUTE DEPLOYMENT AT SUPERSONIC SPEEDS
Kojiro Suzuki and Takashi Abe Dec. 1994 27 p Repr. from Institute of Space and Astronautical Science Report No. 655 (Sagamihara, Japan, Tokyo Univ.), Dec. 1994 p 1-24
(ISSN 0285-6808)
(ISAS-R-655) Avail: CASI HC A03/MF A01

The wake flow field behind the EXPRESS capsule at supersonic speeds is studied experimentally in the wind tunnel. The schlieren photographs and the measurements of the Pitot pressure and the static pressure in the wake clarify the structure of the wake flow field and the effects of the freestream Mach number on it. The wake structure is classified into two types, that is, the subsonic wake neck type and the supersonic wake neck type. The flow characteristics of each wake neck type are discussed. From a viewpoint of the parachute deployment, the effects of the freestream Mach number on the dynamic pressure in the wake are investigated. The recovery ratio of the dynamic pressure in the wake increases with the decrease in the Mach number. At lower Mach number, however, the recovery is delayed due to the extension of the recirculating region behind the capsule bottom. The numerical simulations of the wake flow field are carried out by solving the laminar Navier-Stokes equations and it is pointed out that the recovery of the flow velocity and the dynamic pressure may be enhanced significantly by the turbulent transition on the wake trail. DEVELOPMENT OF AN UPWIND, FINITE-VOLUME CODE WITH FINITE-RATE CHEMISTRY Final Report, 1 Aug. 1994 - 31 Jan. 1995
Gregory A. Molvik Jan. 1995 19 p Original contains color illustrations
(Contract NCC2-498)
(NASA-CR-197747; NAS 1.26:197747; MCAT-95-01) Avail: CASI HC A03/MF A01; 5 functional color pages

Under this grant, two numerical algorithms were developed to predict the flow of viscous, hypersonic, chemically reacting gases over three-dimensional bodies. Both algorithms take advantage of the benefits of upwind differencing, total variation diminishing techniques and of a finite-volume framework, but obtain their solution in two separate manners. The first algorithm is a zonal, time-marching scheme, and is generally used to obtain solutions in the subsonic portions of the flow field. The second algorithm is a much less expensive, space-marching scheme and can be used for the computation of the larger, supersonic portion of the flow field. Both codes compute their interface fluxes with a temporal Riemann solver and the resulting schemes are made fully implicit including the chemical source terms and boundary conditions. Strong coupling is used between the fluid dynamic, chemical and turbulence equations. These codes have been validated on numerous hypersonic test cases and have provided excellent comparison with existing data. This report summarizes the research that took place from August 1,1994 to January 1, 1995. Author

A NUMERICAL METHOD FOR UNSTEADY TRANSONIC FLOW ABOUT WINGS WITH CONTROL SURFACES
Tao Yu and Jianbai Zhang 15 Dec. 1994 17 p Transl. into ENGLISH from Kongqidonglixue Xuebao (China), v. 9, no. 3, Sep. 1991 p 338-343 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289631; NAIC-ID(RS)T-0920-92) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This article introduces a type of finite difference calculation method for unsteady transonic speed flows associated with wings having control surfaces. The equations which are chosen for use are modified three dimensional nonsteady transonic speed small perturbation geopotential equations. Use is made of time integration methods. Solution forms are approximate factor type resolutions of alternating direction implicit (ADI) type forms. Use is made of this type of method to calculate the unsteady aerodynamic forces associated with F-5 wings in oncoming flows with Mach numbers of 0.9 and 0.925 as well as the unsteady aerodynamic forces associated with control surface oscillations. Comparisons were carried out of calculation results with NLR test results from outside of China and calculation results from XTRAN3S methods. This clearly showed that calculations were successful. A NEW DRAG MEASUREMENT SYSTEM FOR WIND TUNNEL TESTING OF THE RACING BICYCLE AND RIDER TO DETERMINE A LOW DRAG CONFIGURATION M.S. Thesis

Brian A. Parker Dec. 1994 92 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289375; AFIT/GAE/ENY/94D-17) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study investigated the application of splitter plate effects to reduce the aerodynamic drag of the racing bicycle and rider system. A sensitive, low-force, beam-type, single-component balance was developed to provide drag measurements accurate to within 0.053 N (0.012 lbf). The performance of the new system was verified by comparing the measured drag on a three-dimensioaal, right-circular cylinder model, 0.127 m (5.0 in) in diameter and 0.610 m (24 in) long, with the results from a commercial balance and a other similar data. The bicycle and rider model consisted of a full-scale mannequin comprising only the hips, legs and feet, mounted on a regulation 0.48 m (19 in) size bicycle. Rotation of the wheels and a stationary ground plane were also simulated. Two frame configurations in conjunction with a disk type wheel were tested to determined the lowest drag configuration for narrow and wide spacing of the rider's legs. The results show that for the standard tube construction frame, the conventional wisdom to streamline as much as possible prevails. When an aerodynamic frame was tested, the overall drag was reduced. Although the standard spacing still provided the lowest drag configuration, any further streamlining showed an increase in drag. DTIC

PERFORMANCE CHARACTERIZATION OF A HIGHLY-OFFSET DIFFUSER WITH AND WITHOUT BLOWING VORTEX GENERATOR JETS M.S. Thesis

Michael B. Senseney Dec. 1994 191 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289334; AFIT/GAE/ENY/94D-14) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The effect of blowing vortex generator jets (VGJ's) on the performance of a highly-offset (s-duct) diffuser was investigated experimentally. VGJ's are pitched, skewed jets which generate streamwise vortices as well as injecting high-momentum fluid into the boundary layer. Diffuser performance with and without VGJ's was measured for an inlet Mach number of 0.6 (Re/x = l.27e7 per cm). Pitot static and hot-film instrumentation was used to measure flow properties at the diffuser inlet and exit planes. Without blowing, the flow on the lower surface of the diffuser was massively separated. Blowing at 0.48% mass flow ratio through three lower-surface VGJ's reduced the size of the separated flow region, reduced the thickness of the boundary layer at the exit plane, increased pressure recovery by 1.3%, and increased the static pressure rise achieved in the diffuser by over 50%. Turbulence intensity, turbulent shear stress, and turbulent kinetic energy were reduced as well. Distortion of the exit plane flowfield increased with blowing. DTIC

CALCULATION OF THREE-DIMENSIONAL (3-D) INTERNAL FLOW BY MEANS OF THE VELOCITY-VORTICITY FORMULATION ON A STAGGERED GRID

Paul M. Stremel May 1995 35 p
(RTOP 505-59-36)
(NASA-TM-110352; A-950063; NAS 1.15:110352) Avail: CASI HC A03/MF A01

A method has been developed to accurately compute the viscous flow in three-dimensional (3-D) enclosures. This method is the 3-D extension of a two-dimensional (2-D) method developed for the calculation of flow over airfoils. The 2-D method has been tested extensively and has been shown to accurately reproduce experimental results. As in the 2-D method, the 3-D method provides for the non-iterative solution of the incompressible Navier-Stokes equations by means of a fully coupled implicit technique. The solution is calculated on a body fitted computational mesh incorporating a staggered grid methodology. In the staggered grid method, the three components of vorticity are defined at the centers of the computational cell sides, while the velocity components are defined as normal vectors at the centers of the computational cell faces. The staggered grid orientation provides for the accurate definition of the vorticity components at the vorticity locations, the divergence of vorticity at the mesh cell nodes and the conservation of mass at the mesh cell centers. The solution is obtained by utilizing a fractional step solution technique in the three coordinate directions. The boundary conditions for the vorticity and velocity are calculated implicitly as part of the solution. The method provides for the non-iterative solution of the flow field and satisfies the conservation of mass and divergence of vorticity to machine zero at each time step. To test the method, the calculation of simple driven cavity flows have been computed. The driven cavity flow is defined as the flow in an enclosure driven by a moving upper plate at the top of the enclosure. To demonstrate the ability of the method to predict the flow in arbitrary cavities, results will he shown for both cubic and curved cavities. Author

WIND-TUNNEL TEST OF THE S814 THICK ROOT AIRFOIL

D. M. Somers (Airfoils, Inc., State College, PA.) and J. L. Tangler Jan. 1995 7 p Presented at the 1995 American Society of Mechanical Engineers (ASME) Energy Sources Technology Conference and Exhibition, Houston, TX, 29 Jan. - 1 Feb. 1995
(Contract DE-AC36-83CH-10093)
(DE95-000268; NREL/TP-442-7388; CONF-950116-7) Avail: CASI HC A02/MF A01

The objective of this wind-tunnel test was to verify the predictions of the Eppler Airfoil Design and Analysis Code for a very thick airfoil having a high maximum lift coefficient c(sub L,max) designed to be largely insensitive to leading edge roughness effects. The 24-percent-thick S814 airfoil was designed with these characteristics to accommodate aerodynamic and structural considerations for the root region of a wind-turbine blade. In addition, the airfoil's maximum lift-to-drag ratio was designed to occur it a high lift coefficient. To accomplish the objective, a two-dimensional wind-tunnel test of the S814 thick root airfoil was conducted in January 1994 in the low-turbulence wind tunnel of the Delft University of Technology Low Speed Laboratory. Data were obtained for transition-free and transition-fixed conditions at Reynolds numbers of 0.7, 1.0, 1.5, 2.0, and 3.0 x 10(exp 6). For the design Reynolds numbers of 1.5 x 10(exp 6), the transition-free c(sub L,max) is 1.3 which satisfies the design specification. However, this value is significantly lower than the predicted c(sub L,max) of almost 1.6. With transition-fixed at the is 1.2. The difference in c(sub L,max) between the transition-free and transition-fixed conditions demonstrates the airfoil's minimal sensitivity to roughness effects. The

S814 root airfoil was designed to complement existing NREL low c(sub L,max) tip-region airfoils for rotor blades 10 to 15 meters in length. DOE

A GENERAL THEORY OF TWO- AND THREE-DIMENSIONAL ROTATIONAL FLOW IN SUBSONIC AND TRANSONIC TURBOMACHINES Final Report
Chung-Hua Wu May 1993 241 p
(Grant NAG3-1072; RTOP 505-90-21; RTOP 335-05-01)
(NASA-CR-4496; E-7267; NAS 1.26:4496) Avail: CASI HC A11/MF A03

This report represents a general theory applicable to axial, radial, and mixed flow turbomachines operating at subsonic and supersonic speeds with a finite number of blades of finite thickness. References reflect the evolution of computational methods used, from the inception of the theory in the 50's to the high-speed computer era of the 90's. Two kinds of relative stream surfaces, S(sub 1) and S(sub 2), are introduced for the purpose of obtaining a three-dimensional flow solution through the combination of two-dimensional flow solutions. Nonorthogonal curvilinear coordinates are used for the governing equations. Methods of computing transonic flow along S(sub 1) and S(sub 2) stream surfaces are given for special cases as well as for fully three-dimensional transonic flows. Procedures pertaining to the direct solutions and inverse solutions are presented. Information on shock wave locations and shapes needed for computations are discussed. Experimental data from a Deutsche Forschungs- und Versuchsanstalt fur Luft- und Raumfahrt e.V. (DFVLR) rotor and from a Chinese Academy of Sciences (CAS) transonic compressor rotor are compared with the computed flow properties. Author (revised)

This report summarizes accomplishments and progress for the period ending April 1995. Much of the work during this period has concentrated on preparation for an analysis of data produced by an extensive wind tunnel test. Time has also been spent further developing an empirical theory to account for the effects of blade-vortex interaction upon the circulation distribution of the vortex and on preliminary measurements aimed at controlling the vortex core size. TranAir: A FULL-POTENTIAL, SOLUTION-ADAPTIVE, RECTANGULAR GRID CODE FOR PREDICTING SUBSONIC, TRANSONIC, AND SUPERSONIC FLOWS ABOUT ARBITRARY CONFIGURATIONS. USER'S MANUAL
F. T. Johnson, S. S. Samant, M. B. Bieterman, R. G. Melvin, D. P. Young, J. E. Bussoletti, and C. L. Hilmes Dec. 1992 198 p
(Contract NAS2-12513; RTOP 505-61-21)
(NASA-CR-4349; A-90092; NAS 1.26:4349) Avail: CASI HC A09/MF A03

The TranAir computer program calculates transonic flow about arbitrary configurations at subsonic, transonic, and supersonic freestream Mach numbers. TranAir solves the nonlinear full potential equations subject to a variety of boundary conditions modeling wakes, inlets, exhausts, porous walls, and impermeable surfaces. Regions with different total temperature and pressure can be represented. The user's manual describes how to run the TranAir program and its graphical support programs. Author

MEASUREMENTS OF STORE FORCES AND MOMENTS AND CAVITY PRESSURES FOR A GENERIC STORE IN AND NEAR A BOX CAVITY AT SUBSONIC AND TRANSONIC SPEEDS
Robert L. Stallings, Jr. (Lockheed Engineering and Sciences Co., Hampton, VA.), E. B. Plentovich, M. B. Tracy, and Michael J. Hemsch (Lockheed Engineering and Sciences Co., Hampton, VA.) May 1995 178 p
(RTOP 505-68-70-09)
(NASA-TM-4611; L-17388; NAS 1.15:4611) Avail: CASI HC A09/MF A02

An experimental force and moment study was conducted in the Langley 8-Foot Transonic Pressure Tunnel for a generic store in and near rectangular box cavities contained in a flat-plate configuration at subsonic and transonic speeds. Surface pressures were measured inside the cavities and on the flat plate. The length-to-height ratios were 5.42, 6.25, 10.83, and 12.50. The corresponding width-to-height ratios were 2.00, 2.00, 4.00, and 4.00. The free-stream Mach number range was from 0.20 to 0.95. Surface pressure measurements inside the cavities indicated that the flow fields for the shallow cavities were either closed or transitional near the transitional/closed boundary. For the deep cavities, the flow fields were either open or near the open/transitional boundary. The presence of the store did not change the type of flow field and had only small effects on the pressure distributions. For transitional or open transitional flow fields, increasing the free-stream Mach number resulted in large reductions in pitching-moment coefficient. Values of pitching-moment coefficient were always much greater for closed flow fields than for open flow fields. Author

A new computer program, called TranAir, for analyzing complex configurations in transonic flow (with subsonic or supersonic freestream) was developed. This program provides accurate and efficient simulations of nonlinear aerodynamic flows about arbitrary geometries with the ease and flexibility of a typical panel method program. The numerical method implemented in TranAir is described. The method solves the full potential equation subject to a set of general boundary conditions and can handle regions with differing total pressure and temperature. The boundary value problem is discretized using the finite element method on a locally refined rectangular grid. The grid is automatically constructed by the code and is superimposed on the boundary described by networks of panels; thus no surface fitted grid generation is required. The nonlinear discrete system arising from the finite element method is solved using a preconditioned Krylov subspace method embedded in an inexact Newton method. The solution is obtained on a sequence of successively refined grids which are either constructed adaptively based on estimated solution errors or are predetermined based on user inputs. Many results obtained by using TranAir to analyze aerodynamic configurations are presented. Author

CONSTRUCTION AND WIND TUNNEL TEST OF A 1/12TH SCALE HELICOPTER MODEL Master's Thesis
Michael A. Capasso Sep. 1994 82 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288487) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis reports on the construction of a 1/12th scale model of the award winning Arapaho attack helicopter design and wind tunnel test to determine both the model and full scale equivalent flat plate area. Tests were conducted for lg level flight and included yawed flight conditions up to 10 degrees. The significance of equivalent flat plate area for helicopters is that it is the principal parameter that establishes rotor propulsive force requirements. The Model was constructed from the original design submitted by the 1993 NPS Helicopter Design Team and is 47.5 inches long with a 48-inch main rotor diameter. The model was tested in the NPS Low Speed Wind Tunnel to measure the drag force on the main body of the model at wind tunnel velocities up to 72 knots. Drag force on the model was also measured with the rotor head and longbow radome installed, and at various yaw angles up to 10 degrees. The equivalent flat plate area was then calculated from these measurements and compared to other helicopters. Recommendations for further wind tunnel testing were made. DTIC

STUDY OF POTENTIAL AERODYNAMIC BENEFITS FROM SPANWISE BLOWING AT WINGTIP Ph.D. Thesis - George Washington Univ., 1992
Raymond E. Mineck Jun. 1995 102 p
(RTOP 505-59-10-30)
(NASA-TP-3515; L-17368; NAS 1.60:3515) Avail: CASI HC A06/MF A02

Comprehensive experimental and analytical studies have been conducted to assess the potential aerodynamic benefits from spanwise blowing at the tip of a moderate-aspect-ratio swept wing. Previous studies on low-aspect-ratio wings indicated that blowing from the wingtip can diffuse the tip vortex and displace it outward. The diffused and displaced vortex will induce a smaller downwash at the wing, and consequently the wing will have increased lift and decreased induced drag at a given angle of attack. Results from the present investigation indicated that blowing from jets with a short chord had little effect on lift or drag, but blowing from jets with a longer chord increased lift near the tip and reduced drag at low Mach numbers. A Navier-Stokes solver with modified boundary conditions at the tip was used to extrapolate the results to a Mach number of 0.72. Calculations indicated that lift and drag increase with increasing jet momentum coefficient. Because the momentum of the jet is typically greater than the reduction in the wing drag and the increase in the wing lift due to spanwise blowing is small, spanwise blowing at the wingtip does not appear to be a practical means of improving the aerodynamic efficiency of moderate-aspectratio swept wings at high subsonic Mach numbers.

A methodology is described for computing viscous flows of air and sulfur hexafluoride (SF6). The basis is an existing flow solver that calculates turbulent flows in two dimensions on unstructured triangular meshes. The solver has been modified to incorporate the thermodynamic model for SF6 and used to calculate the viscous flow over two multielement airfoils that have been tested in a wind tunnel with air as the test medium. Flows of both air and SF6 at a free-stream Mach number of 0.2 and a Reynolds number of 9 x 10(exp 6) are computed for a range of angles of attack corresponding to the wind-tunnel test. The computations are used to investigate the suitability of SF6 as a test medium in wind tunnels and are a follow-on to previous computations for single-element airfoils. Surface-pressure, lift, and drag coefficients are compared with experimental data. The effects of heavy gas on the details of the flow are investigated based on computed boundary-layer and skin-friction data. In general, the predictions in SF6 vary little from those in air. Within the limitations of the computational method, the results presented are sufficiently encouraging to warrant further experiments. Author

THE 1994 UPDATED NATIONAL AIRSPACE SYSTEM PERFORMANCE ASSESSMENT FOR YEAR 2005

Douglas Baart and Anny Cheung Oct. 1994 31 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A288652; DOT/FAA/CT-TN94/41; FAA-AOR-100-94-009) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report documents the evaluation of the National Airspace System (NAS) performance for year 2005. The National Airspace System Performance Analysis Capability (NASPAC) Simulation Modeling System (SMS) was used to simulate the future air traffic control (ATC) system. Airport airfield and technological improvements expected to be completed by year 2005 were included in this analysis. Future air traffic demand was based on the 1993 Terminal Area Forecasts (TAF). The study results indicate that most of the delay in the system for year 2005 is caused by airfield capacity limitations. Three-fourths of the delay is related to ground operations or ground manifestation of airspace congestion. About 45 percent of the total delay is related to ground operations or ground manifestation of airspace congestion. About 45 percent of the total delay is attributed to adverse weather. Airports that have no future airfield improvements planned show the highest delay estimates. DTIC

AIRCRAFT FUEL SYSTEM LIGHTNING PROTECTION DESIGN AND QUALIFICATION TEST PROCEDURES DEVELOPMENT Final Report

Keith E. Crouch Sep. 1994 193 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DTFA03-92-C-00003)

(AD-A288401; LT-94-1067; DOT/FAA/CT-94/74) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Navy and the Air Force recognized the need for improved test procedures for evaluating the lightning protection design of aircraft fuel systems. Under their sponsorship, a program to develop adjustable, standard ignition sources which could be used to calibrate techniques for detecting ignition sources during lightning testing was established. The minimum ignition levels of voltage sparks and hot spots were established under the program before it was terminated due to funding problems. The present program under FAA sponsorship, is a continuation of the original program. The Standard Voltage Spark Ignition Source and the Standard Hot Spot Ignition Source were completed and documented. The most promising approach for developing a Standard Thermal Spark Ignition Source was determined and is presented. Photographic detection techniques were investigated and the limitations determined. The presence of light on a photographic film indicated the possibility of an ignition source but can not confirm the ignition probability (if any). Hydrogen mixtures appear to provide the ability to have adjustable ignition probabilities and low energy (low over-pressure) ignitions. DTIC

CHARACTERIZATION OF CORROSION AND DEVELOPMENT OF A BREADBOARD OF A D SIGHT AIRCRAFT INSPECTION SYSTEM, PHASE 1 Final Report

F. Karpala and O. L. Hageniers Aug. 1994 369 p Sponsored by FAA Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A288347; DOT/FAA/CT-94/56) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report presents Phase 1 results of a joint Project Arrangement between the FAA and Transport Canada Aviation for the development and testing of a nondestructive inspection (NDI) system for aircraft corrosion detection in fuselage lap joints. The process is based on D Sight, an optical technique developed by Diffracto Limited. This research project had the following major components: (1) identification of corrosion areas of concern; (2) collection of corrosion samples; (3) acceleration of specimen corrosion in the laboratory; (4) construction and testing of a breadboard inspection device; and (5) laboratory and field trials of the breadboard device. The outcome can be summarized as follows: (1) a library of aircraft corrosion samples has been established; (2) a corrosion process has been developed that matches in-service corrosion well, (3) a breadboard D Sight NDI system has been built and tested; and (4) a proposal for follow-on work has been completed. THE USE OF ELECTROCHEMISTRY AND ELLIPSOMETRY FOR IDENTIFYING AND EVALUATING CORROSION ON AIRCRAFT Monthly Report, 15 Sep. - 14 Oct. 1994

Chester M. Dacres 14 Oct. 1994 2 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F49620-94-C-0042)

(AD-A288536; AFOSR-94-0687TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The reporting for this period and the data from the feasibility study show that the signature from the corroding aircraft is repeatable. The first template design for the paint application was abandoned due to the conductive paint consistency. A more practical approach, using adhesive tape to lay the grid pattern, proved a better technique for paint application. Silver paint was added to the test, because it is lower than gold paint in cost and has better electrical conductivity than carbon paint. The conductivity of gold paint increases with cure temperature, which could adversely alter the coating integrity. A cure temperature of 50 C was established for all paints to maintain coating integrity. Last, using the AC Impedance technique, it was found that the two-electrode approach is ideally suited for in-situ real-time analysis of metal/coating systems. CASI

FURTHER INVESTIGATIONS OF ICING EFFECTS ON AN ADVANCED HIGH-LIFT MULTI-ELEMENT AIRFOIL

Dean Miller, Jaiwon Shin, David Sheldon, Abdollah Khodadoust (McDonnell-Douglas Aerospace, Long Beach, CA.), Peter Wilcox (McDonnell-Douglas Aerospace, Long Beach, CA.), and Tammy Langhals (NYMA, Inc., Brook Park, OH.) May 1995 19 p Presented at the Applied Aerodynamics Conference, San Diego, CA, 19-22 Jun. 1995; sponsored by AIAA

(Contract NAS3-27186; RTOP 505-68-10)

(NASA-TM-106947; E-9683; NAS 1.15:106947; AIAA Paper 95-1880)

Avail: CASI HC A03/MF A01

In 1993 an experimental effort was initiated to investigate the effect of ice accretions on an advanced high-lift, multi-element airfoil. This airfoil is representative of an advanced transport wing, and has a state-of-the-art three element high lift system. This experimental effort is part of a cooperative program between McDonnell Douglas Aerospace and the NASA Lewis Research Center. The goal of this program is to improve the current understanding of ice accretion characteristics on multi-element airfoils. One key objective of this program is to establish an experimental database of multi-element ice accretions using the NASA-Lewis Icing Research Tunnel (IRT). The first multi-element icing test in this cooperative effort was conducted in 1993. A second 'follow on' icing test was conducted in 1994, for the purpose of augmenting the multi-element ice accretion database obtained in 1993, and also for studying the effect of flap gap setting on ice accretions. This paper presents selected results from the 1994 multi-element icing test, and will emphasize the effect of angle-of-attack, and flap gap setting on multi-element ice accretions. Author

A REVIEW OF FALCONRY AS A BIRD CONTROL TECHNIQUE WITH RECOMMENDATIONS FOR USE AT THE SHUTTLE LANDING FACILITY, JOHN F. KENNEDY SPACE CENTER, FLORIDA, USA

Vickie L. Larson (Bionetics Corp., Cocoa Beach, FL.), Sean P. Rowe (Bionetics Corp., Cocoa Beach, FL.), David R. Breininger (Bionetics Corp., Cocoa Beach, FL.), and Reuven Yosef (Archbold Biological Station, Lake Placid, FL.) Jun. 1994 47 p
(Contract NAS10-11624)
(NASA-TM-110142; NAS 1.15:110142) Avail: CASI HC A03/MF A01

Falconry has been proposed as a method of reducing the bird/aircraftstrike hazard, in addition to current bird control techniques, at the Shuttle Landing Facility (SLF), John F. Kennedy Space Center (KSC), Florida, U.S. Bird control programs using falconry have been employed at a number of military and commercial airfields in the U.S., Canada, and Europe. Most falconry programs have been discontinued. In most situations, falconry did not prove cost effective when compared to alternative bird control techniques. Available literature and documents, as well as several raptor specialists and military personnel, suggest that falconry may be useful only against certain problem species and when other bird control methods have been proven inadequate. Because many of the most commonly used falcons are protected species, acquisition of falcons will complicate their use in bird control programs. Many avian species found at the SLF are federally and state protected or of conservation concern, therefore, environmental impacts may also result from the use of falcons. Author

THE PERFORMANCE OF CARGO AIRDROP SYSTEMS USING G-12E PARACHUTES: STATISTICAL DETERMINATION OF MINIMUM ALTITUDE Final Report, Mar. 1993 - Nov. 1994

Steven E. Kunz Feb. 1995 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A291666; NATICK/TR-95/017) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In order to reduce the exposure of aircraft to hostile fire, the U.S. Air Force is interested in dropping cargo from the lowest possible altitude above ground level. Using trajectory data from previous airdrop system testing, this report statistically determines the minimum altitude above ground level (AOL) from which airdrop systems (comprising clusters of two to three G-12E parachutes) may safely deliver cargoes up to 5000 pounds. The methods used to compute variables of interest, such as system tension and system orientation, are presented. To support this statistical analysis, intervals were defined based upon clearly discernible events. This led to a reexamination of so-called functional phases, used by the airdrop community. Some phases were found unsuitable for statistical purposes. To resolve this problem, process intervals were defined based upon clearly discernible process states or events. Based upon the limited data available, it was found that G-12E airdrop systems can safely deliver cargoes of up to 5000 pounds when released from aircraft at an altitude of approximately 300 feet AGL. ROTORCRAFT CRASHWORTHY AIRFRAME AND FUEL SYSTEM TECHNOLOGY DEVELOPMENT PROGRAM Final Report

Joseph W. Coltman Oct. 1994 175 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DTFA03-84-R-40032)
(AD-A289986; TR-90425; DOT/FAA/CT-91/7) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A research program was initiated by the Federal Aviation Administration (FAA) Technical Center to investigate crash resistance design technology applicable to U.S. civil rotorcraft. The purpose of the program was to identify crash resistance design technology consistent with rotorcraft type, primary use, and the expected crash environments for civil helicopters. The program examined crash resistance technology for landing gear, fuselage structure, seating systems, and fuel systems. A trade-off study was conducted to identify an optimum level of crash resistance for three weight classes of civil rotorcraft. The results of the research program were a series of crash impact design and test criteria for civil rotorcraft, as well as an assessment of the weight penalties that would be incurred in meeting these criteria. The program was conducted by Simula Inc. with assistance from Bell Helicopter Textron Inc. and Sikorsky Aircraft. DTIC

The Federal Aviation Administration's (FAA) air traffic control (ATC) services are provided by Air Route Control Centers (ARTCC's), Combined Center Radar Approach Controls (CERAP's), Terminal Radar Approach Control (TRACON) facilities, and Air Traffic Control Towers (ATCT's). TRACON's are subdivided into Metroplex Control Facilities (MCF's) and standalone facilities. The modernization of these facilities will be based upon operational and economic considerations. This report serves as an inventory reference document for high level operational facility planning and requirements' development. The report presents a current and projected pictorial description of ATC facilities arranged by ARTCC geographic boundaries. All FAA and Department of Defense (DOD) radar facilities and their associated control towers are included. Included is information on radar connectivities, automation equipment, tower display systems, radar operational positions, and air traffic staffing. DTIC

FLIGHT EVALUATION OF GPS/DGPS SENSOR SYSTEMS INSTALLED IN NAL Do228

Kazutoshi Ishikawa, Takatsugu Ono, Masaaki Murata, Toshiaki Tsujii, Hitoshi Mineno (National Space Development Agency, Tokyo, Japan.), and Shuichi Matsumoto (National Space Development Agency, Tokyo, Japan.) Mar. 1994 87 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1230) Avail: CASI HC A05/MF A01

Navigation systems have been tested with a Dornier 228-200 (Do228), experimental research airplane of the National Aerospace Laboratory (NAL) at Sendai airport, Japan. A C/A code single channel Global Positioning System (GPS) receiver (Rockwell/Collins Navcore 1) was installed in the Do228. The receiver can operate in real-time differential GPS (DGPS) during differential corrections coming from a GPS base station operated at a known position. The base station will track up to four visible satellites and measure the error in pseduo-range to each tracked satellite, based on broadcast emphemeris data and known position. A laser tracker was used to determine a reference trajectory of the airplane. Navigation accuracy of the onboard receiver is evaluated by direct comparison between reference trajectories and sensor outputs. Position accuracies of the GPS receiver are determined by pseudo-range errors between satellites and receiver. These ranging errors include common errors and receiver's specific residual errors. For all GPS receivers located within 200 kilometers of each other, common errors include satellite clock error, ephemeris error, refraction (ionospheric/tropospheric delay) and selective availability (SA) error. This paper describes GPS/DGPS accuracies during approach and landing of the aircraft. All data in which GDOP is less than five are divided into three cases: (1) stand-alone navigation with SA, (2) differential navigation with SA and (3) stand alone navigation without SA tested on January 1991. Stand-alone navigation accuracy under no SA is 20 meters, that is because the receiver's specific errors are more than common errors. The effectiveness of DGPS under SA was demonstrated by flight experiments. Author

FLIGHTPATH SYNTHESIS AND HUD SCALING FOR V/STOL TERMINAL AREA OPERATIONS (Diskette)
Vernon K. Merrick and James A. Jeske Apr. 1995 46 p Diskette: 3.5-inch Mac diskette
(RTOP 505-59-36)
(NASA-TM-110348; A-950052; NAS 1.15:110348; NONP-NASA-DK-95-48301) Avail: CASI SET A05 (HC,DK)

A two circle horizontal flightpath synthesis algorithm for Vertical/Short Takeoff and Landing (V/STOL) terminal area operations is presented. This algorithm provides a flightpath that is tangential to the aircraft's velocity vector at the instant of flightpath select and has continuous curvature. The algorithm corrects deficiencies noted in tests conducted with the V/STOL Systems Research Aircraft (VSRA) using a single circle algorithm described in NASA TM 104027. In addition, a more general vertical flightpath synthesis algorithm is presented, aimed primarily at minimizing the rapid increase of pilot workload during the final phase of decelerating transition just prior to acquiring the station-keeping point. Finally, a new technique for lateral scaling of a V/STOL Head Up Display (HUD) is presented, aimed at minimizing the inevitable anomalies that such scaling produces. All the above named items have been tested in flight with the VSVR, and all have produced improvements. Author

ANALYSIS AND SIMULATION OF NARROWBAND GPS JAMMING USING DIGITAL EXCISION TEMPORAL FILTERING M.S. Thesis
Gerald L. Falen Dec. 1994 187 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289328; AFIT/GE/ENG/94D-09) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this thesis is to investigate the performance of the Digital Excision Temporal Filter (DETF) to reject narrowband jammers used against the Global Positioning System (GPS). The DETF takes the Fast Fourier Transform (FFT) of the GPS signal and excises any FFT bins that are above a preselected threshold level. Then the excised signal is Inverse Fourier Transformed and fed to the GPS receiver. Several jammer types are simulated including Continuous Wave (CW), Pulse CW, Swept CW, Narrowband Spot Noise, and Wideband Barrage Noise jammers. Cases are also simulated using all but the Wideband Barrage Noise jammer at one time. The DETF can effectively reject all of the types of jammers simulated except for the Wideband Barrage Noise jammer. The DETF degrades the GPS system performance in the presence of the Wideband Barrage Noise jammer. In an actual DETF implementation, the excision threshold should be set from six to nine dB above the excision cutoff level, where the excision cutoff level is equal to the GPS signal strength plus receiver thermal noise level. THE CONTROLLER MEMORY GUIDE. CONCEPTS FROM THE FIELD
Earl S. Stein and Jim Bailey Sep. 1994 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289263; DOT/FAA/CT-TN94/28) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Memory is an elusive human ability which both helps and hinders air traffic controllers' performance. This document was developed based on the ideas of controllers themselves when they were asked what they did to manage their memory resources. The guide is a job aide meant to help controllers think about what they do and about the little things they could use to help them reduce the possibilities for errors based on memory lapses. The material is presented in graphical cartoon format along with a very direct and minimalized text narrative. The goal was to provide the concepts in a readable format that controllers could review when they had the time. The issues covered in the guide all relate to memory in one way or another, but in many cases transcend memory issues alone, and look at the more basic issue of any person-machine system performance. Human and system performance are the bottom line in any complex command and control system such as air traffic control. DTIC

AN INTEGRATED GPS/INS/BARO AND RADAR ALTIMETER SYSTEM FOR AIRCRAFT PRECISION APPROACH LANDINGS M.S. Thesis
Robert A. Gray Dec. 1994 265 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289280; AFIT/GE/ENG/94D-13) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Currently, the Department of Defense (DOD) and the commercial airline industry are utilizing the Instrument Landing System (ILS) during aircraft landings for precision approaches. The replacement system for the aging ILS was thought to he the Microwave Landing System (MLS). Instead, use of the Global Positioning System (GPS) is now thought to be a viable replacement for ILS precision approaches. The majority of current precision landing research has exploited 'stand-alone' GPS receiver techniques. This thesis instead explores the possibilities of using an extended Kalman filter (EKF) that integrates an Inertial Navigation System (INS), GPS, Barometric Altimeter, Pseudolite and Radar Altimeter for aircraft precision approaches. This thesis shows that integrating the INS, GPS, Barometric Altimeter and Radar Altimeter meets Federal Aviation Administration (FAA) requirements for a Category I precision approach and integrating the INS, GPS, Barometric Altimeter, Radar Altimeter and a single Pseudolite meets FAA requirements for a Category 2 precision approach. PRECISION LANDING SYSTEM MATHEMATICAL MODELING STUDY REPORT FOR ANDREWS AIR FORCE BASE, RUNWAY 19L, CAMP SPRINGS, MD Technical Note, Jun. - Jul. 1993
Jesse Jones, Elliott Rushton, and Ronald Lockhart Nov. 1994 129 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289015; DOT/FAA/CT-TN93/35) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This technical note describes Microwave Landing System (MLS) and Precision Distance Equipment (DME/P) mathematical modeling performed for runway 19L, Andrews Air Force Base (ADW), Camp Springs, Maryland. This study evaluates the effects of scattering and shadowing from selected buildings, hangars, aircraft, and terrain. Results are provided as plots illustrating the predicted multipath levels, separation angles, and the resulting error plots from the worst case contributors. Scenarios were modeled to determine the effects of the multipath sources in the modeled environment. These resulting errors were analyzed and compared to error tolerance (FAA-STD-022d) to determine if the errors are acceptable. The effects of the ADW environment were analyzed and evaluated. It was determined that the proposed site will perform satisfactorily with no changes. DTIC

The basic design considerations for perspective Air Traffic Control displays are described. A software framework has been developed for manual viewing parameter setting (MVPS) in preparation for continued, ongoing developments on automated viewing parameter setting (AVPS) schemes. The MVPS system is based on indirect manipulation of the viewing parameters. Requests for changes in viewing parameter setting are entered manually by the operator by moving viewing parameter manipulation pointers on the screen. The motion of these pointers, which are an integral part of the 3-D scene, is limited to the boundaries of screen. This arrangement has been chosen, in order to preserve the correspondence between the new and the old viewing parameter setting, a feature which contributes to preventing spatial disorientation of the operator. For all viewing operations, e.g. rotation, translation and ranging, the actual change is executed automatically by the system, through gradual transitions with an exponentially damped, sinusoidal velocity profile, in this work referred to as 'slewing' motions. The slewing functions, which eliminate discontinuities in the viewing parameter changes, are designed primarily for enhancing the operator's impression that he, or she, is dealing with an actually existing physical system, rather than an abstract computer generated scene. Current, ongoing efforts deal with the development of automated viewing parameter setting schemes. These schemes employ an optimization strategy, aimed at identifying the best possible vantage point, from which the Air Traffic Control scene can be viewed, for a given traffic situation. Author

DEVELOPMENT OF A CODING FORM FOR APPROACH CONTROL/PILOT VOICE COMMUNICATIONS Final Report

O. V. Prinzo, T. W. Britton, and A. M. Hendrix (Hendrix, Alfred M., Carrizozo, NM.) May 1995 31 p
(Contract DTFA02-91-C-91089)
(DOT/FAA/AM-95/15) Avail: CASI HC A03/MF A01

The Aviation Topics Speech Acts Taxonomy (ATSAT) is a tool for categorizing pilot/controller communications according to their purpose and for classifying communication errors. Air traffic controller communications that deviate from FAA Air Traffic Control Order 7110.65, and pilot communications that depart from the suggested communication in the Airman's Information Manual can be identified and labeled using the error codes provided in the ATSAT. By using the same procedures and tool to analyze communications, direct comparisons can be made between controller phraseology usage in the field and during simulation. Results of a preliminary study to measure inter-coder agreement revealed that novice coders were more dependent on the surface characteristics of the verbatim transcripts and experts relied more on domain specific background knowledge and experience with ATC phraseology to code ATC communications. If a researcher elects to use the ATSAT, we recommend that all coders receive the same orientation and instruction sessions prior to using it. Author

F/A-18 IFOSTP FATIGUE TEST AIRBAG LOAD DETERMINATION ON THE VERTICAL AND HORIZONTAL TAILS

M. F. Lee Jan. 1995 54 p
(DSTO-TR-0135; AR-009-193) Copyright Avail: Issuing Activity (DSTO, Melbourne Victoria, Australia)

A simplistic method for determining discrete loads to approximate a distributed load is shown to have a number of deficiencies, both theoretically and in its practical results. A new method which utilizes Lagrange multipliers is derived and applied to an aerodynamic pressure distribution with improved results. The concept of weighting functions is introduced as a means of comparing the different methods in absolute terms. Weighting functions are also used to assess the effect of removing a load actuator from the standard configuration. Author

DEVELOPMENT OF A NONLINEAR SIMULATION FOR THE MCDONNELL DOUGLAS F-15 EAGLE WITH A LONGITUDINAL TECS CONTROL-LAW M.S. Thesis - Washington Univ.

James P. Dutton, Jr. Sep. 1994 158 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288610; AFIT/CI/CIA/94-136) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this report is to develop using SIMULINK an aircraft simulation that couples the nonlinear equations of motion with the nonlinear aerodynamic and engine performance data. The simulation has been designed using data from actual flight testing of the McDonnell Douglas E-15 Eagle. The ultimate objective is to provide a generic framework for the development of nonlinear simulations of other aircraft with minimal required changes. Design of a longitudinal autopilot using the Total Energy Control System (TECS) concept is accomplished using the linearized model and later validated with the nonlinear model. The model characteristics and the relevant support modules for the F-15 described in are summarized. The numerical data were provided in the format of a Genesis simulation used at Wright-Patterson and the coding was subsequently converted from FORTRAN to MATLAB. A detailed description of the model is in Chapter 2. The evaluation of the open-loop nonlinear model and the design of the TECS control law will be accomplished at the two flight points. Other flight conditions throughout the flight envelope will also be investigated. DTIC

SUPPRESSOR OF OSCILLATIONS IN AIRFRAME CAVITIES Patent

Robert A. Smith, inventor (to Navy), Ephraim Gutmark, inventor (to Navy), Klaus C. Schadow, inventor (to Navy), and Kenneth J. Wilson, inventor (to Navy) 23 Aug. 1994 8 p Filed 14 Feb. 1992
(AD-D017265; US-Patent-5,340,054; US-Patent-Appl-SN-839721; US-Patent-Class-244-1) Avail: US Patent and Trademark Office

The oscillations found to occur in the cavities of a structural frame moving through a fluid are substantially eliminated by the adoption of perturbation elements located at the leading edge of the cavity and reflecting any remaining oscillations out of the cavity at the trailing edge. The perturbation elements may take the form of multiple pins of various shape and geometrical arrangement which prevents the generation and growth of vortices causing acoustic oscillations. The reflection of remaining oscillations out of the cavity may be accomplished by ramping the trailing edge of the cavity. DTIC

EXPERIMENTAL INVESTIGATION OF STATIC AND DYNAMIC GROUND EFFECT ON HOPE ALFLEX VEHICLE

Masashi Shigemi, Akihito Iwasaki, Kenichi Rinoie, Toshimi Fujita, Takeshi Ohnuki, Hidehiko Nakayasu (National Space Development Agency, Tokyo,

Japan.), and Masakazu Sagisaka (National Space Development Agency, Tokyo, Japan.) May 1994 59 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1236) Avail: CASI HC A04/MF A01

A wind tunnel test was conducted to investigate the ground effect on an 8.9% model of the ALFLEX vehicle. The objectives of this experiment were: (1) to make a preliminary inspection of the influence of the new model supporting system on the main flow; (2) to collect data of the static ground effect; and (3) to collect data of the dynamic ground effect. A robot designed for general industrial use was employed as a tool for model support. The model equipped at the tip of the robot arm could be controlled to change its position as well as its pitch, roll and yaw angles. The merits of utilizing the robot in our experiment was not only to raise the efficiency of the static measurements but also to make it possible to collect the dynamic data in the ground effect test. Comparison between results from static and dynamic tests showed that the amount of the dynamic ground effect is no more than the static effect. Author

AEROELASTICITY OF WING AND WING-BODY CONFIGURATIONS ON PARALLEL COMPUTERS Final Report, Feb. 1992 - Jan. 1995
Chansup Byun Jan. 1995 24 p Original contains color illustrations
(Contract NCC2-740)
(NASA-CR-197756; NAS 1.26:197756; MCAT-95-14) Avail: CASI HC A03/MF A01; 7 functional color pages

The objective of this research is to develop computationally efficient methods for solving aeroelasticity problems on parallel computers. Both uncoupled and coupled methods are studied in this research. For the uncoupled approach, the conventional U-g method is used to determine the flutter boundary. The generalized aerodynamic forces required are obtained by the pulse transfer-function analysis method. For the coupled approach, the fluid-structure interaction is obtained by directly coupling finite difference Euler/Navier-Stokes equations for fluids and finite element dynamics equations for structures. This capability will significantly impact many aerospace projects of national importance such as Advanced Subsonic Civil Transport (ASCT), where the structural stability margin becomes very critical at the transonic region. This research effort will have direct impact on the High Performance Computing and Communication (HPCC) Program of NASA in the area of parallel computing. Derived from text

COMPUTATIONAL ANALYSIS OF FOREBODY TANGENTIAL SLOT BLOWING ON THE HIGH ALPHA RESEARCH VEHICLE Final Report
Ken Gee Jan. 1995 57 p Original contains color illustrations
(Contract NCC2-657)
(NASA-CR-197754; NAS 1.26:197754; MCAT-95-11) Avail: CASI HC A04/MF A01; 1 functional color page

A numerical analysis of forebody tangential slot blowing as a means of generating side force and yawing moment is conducted using an aircraft geometry. The Reynolds-averaged, thin-layer, Navier-Stokes equations are solved using a partially flux-split, approximately-factored algorithm. An algebraic turbulence model is used to determine the turbulent eddy viscosity values. Solutions are obtained using both patched and overset grid systems. In the patched grid model, and actuator plane is used to introduce jet variables into the flow field. The overset grid model is used to model the physical slot geometry and facilitate modeling of the full aircraft configuration. A slot optimization study indicates that a short slot located close to the nose of the aircraft provided the most side force and yawing moment per unit blowing coefficient. Comparison of computed surface pressure with that obtained in full-scale wind tunnel tests produce good agreement, indicating the numerical method and grid system used in the study are valid. Full aircraft computations resolve the changes in vortex burst point due to blowing. A time-accurate full-aircraft solution shows the effect of blowing on the changes in the frequency of the aerodynamic loads over the vertical tails. A study of the effects of freestream Mach number and various jet parameters indicates blowing remains effective through the transonic Mach range. An investigation of the force onset time lag associated with forebody blowing shows the lag to be minimal. The knowledge obtained in this study may be applied to the design of a forebody tangential slot blowing system for use on flight aircraft. Author

COMPARISON OF FIXED WING AIRCRAFT ALGORITHMS FOR JANUS M.S. Thesis
Charles L. Daniels, II Sep. 1994 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288503) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research compares the fixed wing altitude algorithms utilized in the United States and the Australian versions of the combat modeling tool, JANUS(A). The Australian Army Battle Simulation Group has recently developed a new algorithm that more realistically models aircraft flight profiles within JANUS(A). A Low-High-Low strike profile was simulated, using both algorithms, against low level, littoral anti-aircraft weaponry. The simulated aircraft were flown in a weapons hold environment and number of detections were recorded over the entire strike route as the principal MOE. The simulated aircraft were then subjected to a weapons free environment where engagement data was compiled. The Australian algorithm enabled the operator to alter aircraft altitude and speed during the simulation on command. The ability to alter altitude and speed are essential to accurately modelling tactical evasive maneuvers. These alterations are not features incorporated in the present U.S. version of JANUS(A). Analysis indicates this controllability not only reduced the number of detections significantly, but also increased aircraft survivability within the strike environment. Both of these phenomenon are expected outcomes of such evasive actions. This work also provided the basis for future work that could incorporate virtual simulation with JANUS(A). DTIC

(AD-A289562; WL-TR-94-3143) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Integrated Mission Precision Attack Cockpit Technology (IMPACT) Program focuses on the analysis, design, and test of cockpit control and display concepts for a single seat, multirole fighter performing precision strike missions against mobile and fixed targets, at night and in adverse weather. This report details the results of the first 'role playing' exercise. This was an exploratory evaluation assessing: (1) pilot workload associated with an air interdiction mission in a single seat fighter; and (2) advanced technologies having the potential to reduce workload and increase mission effectiveness. Subjective workload measures were collected for a baseline

F-15E, conceptual single-seat F-15E, and an Advanced Technology Cockpit (ATC) using the Subjective Workload Assessment Technique (SWAT) and Subjective Workload Dominance (SWORD) technique. Advanced technologies, assumed to be in use in the year 2005, and their possible mechanizations, were rated using questionnaires and interviews. This report describes the role playing methodology and the test results. DTIC

SUPERSONIC CIVIL AIRPLANE STUDY AND DESIGN: PERFORMANCE AND SONIC BOOM Final Report, Jul. 1989 - Jan. 1995
Samson Cheung Jan. 1995 117 p Original contains color illustrations
(Contract NCC2-617)
(NASA-CR-197745; NAS 1.26:197745; MCAT-95-7) Avail: CASI HC A06/MF A02; 11 functional color pages

Since aircraft configuration plays an important role in aerodynamic performance and sonic boom shape, the configuration of the next generation supersonic civil transport has to be tailored to meet high aerodynamic performance and low sonic boom requirements. Computational fluid dynamics (CFD) can be used to design airplanes to meet these dual objectives. The work and results in this report are used to support NASA's High Speed Research Program (HSRP). CFD tools and techniques have been developed for general usages of sonic boom propagation study and aerodynamic design. Parallel to the research effort on sonic boom extrapolation, CFD flow solvers have been coupled with a numeric optimization tool to form a design package for aircraft configuration. This CFD optimization package has been applied to configuration design on a low-boom concept and an oblique all-wing concept. A nonlinear unconstrained optimizer for Parallel Virtual Machine has been developed for aerodynamic design and study. Derived from text

Aircraft pitch response is a vital element of piloted vehicle flying qualities. There has been controversy over both the form and the substance of the requirements for short-term pitch response. Currently, MIL-STD-1797A offers six different methods for evaluating short-term pitch response. These six methods often give conflicting results. Two methods are analyzed in this thesis - the Neal-Smith criteria and the omega(sub sp) Tau(sub theta 2), zeta(sub sp), tau(sub theta) criteria. Domains from both criteria are mapped into each other identifying regions of conflict and regions of agreement. Parametric studies are performed and evaluated for trends. Further, a real-time analysis tool for evaluating these methods is developed. DTIC

AN ANALYSIS OF THE KC-135 THREE-PERSON COCKPIT M.S. Thesis
Robert A. Deivert Dec. 1994 66 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289540; AFIT/GSO/ENS/94D-06) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In an effort to quantitatively determine the utility of mission effectiveness of the KC-135, this research used value-focused thinking to measure the impact of replacing the KC-135 navigator with upgraded avionics. A value model was developed as a hierarchy with fundamental objectives at the highest level and attributes at the lowest level. Weights were assigned to show the contribution each level had to the one above it. The attributes were given a score and an additive model was used to determine utility with and without a navigator. Break-even analysis and net present value calculations were done to show the costs associated with each alternative. This study reveals that the cockpit with the navigator has a higher utility than the cockpit with the upgraded avionics. Value-focused thinking identified additional equipment that would increase the utility of the upgraded avionics. This approach can be used to identify equipment alternatives in the future that add the most utility. This methodology can be used by the Air National Guard to determine whether they should keep navigators as part of the KC-135 crew. DTIC

THE PHOTO-REALISTIC AFIT VIRTUAL COCKPIT M.S. Thesis
Milton E. Diaz Dec. 1994 115 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289376; AFIT/GCS/ENG/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Air Force Institute of Technology (AFIT) has pursued research in virtual environments since 1988. This research expands the current capabilities of the AFIT Virtual Cockpit (VC) by increasing the realism of the cockpit environment and improving the pilot's command interface. Realism is improved creating console elements from texture maps and polygonal models; these elements include working dials, switches and circuit breakers. The pilot command interface is improved in part by adapting the AFIT Information Pod using a two-dimensional mouse input to the virtual three-dimensional environment. This immersive virtual environment is also improved by modifications to the Head Mounted Display (HMD) reducing jitter and allowing the simulation pilot to adjust his/her position within the cockpit. THE EFFECTS OF UH-1 EXPERIENCE ON UH-60 SIMULATOR PERFORMANCE: A PRELIMINARY STUDY Final Report
Charles A. Salter, John A. Caldwell, Jr., John S. Crowley, and Ronald L. Smith Nov. 1994 35 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 3M1-62787-A-879)
(AD-A289457; USAARL-95-4) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Efforts to expand the pool of volunteers for research in the UH-60 simulator prompted USAARL to determine whether UH-1 pilots could be used as an alternative to UH-60 subjects. In this quasi-experimental preliminary study, eight UH-1 pilots were provided with training in the UH-60 simulator. Afterwards, they were required to fly a standardized profile, parts of which had been used in an earlier investigation with UH-60 pilots. The performance accuracy of the groups (UN-1 versus UH-60) were compared on equivalent maneuvers. Results showed that the UH-1 pilots used in this initial study actually performed better on most maneuvers than did the UH-60 pilots who were used in an earlier investigation. Thus, it appears that UH-1 pilots, who are easier to recruit than rated UH-60 pilots, may be suitable as subjects in future simulator studies involving basic instrument pilotage skills. However, before drawing definitive conclusions, these results should be replicated in a controlled study where the pilots are randomly assigned to training and testing conditions during a more limited time frame. AH-1F COBRA REWIRE PROGRAM MANPRINT ANALYSIS
Robert A. Clarke and William J. Boltralik 31 Aug. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DABT60-90-D-0010)
(AD-A289190) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this analysis was to review and analyze the AH-1F Cobra Rewire Program from a MANPRINT perspective. This was accomplished through examination of the AH-1F Cobra Rewire Program documentation and its technical publication, the Cobra Helicopter Rewire

Manual (CHRM). Review of this program's documentation was conducted to identify MANPRINT deficiencies and develop corrective recommendations that ensure the CHRM would mitigate these shortcomings. The scope of this effort was primarily confined to the AH-1F Cobra Rewire Programs CHRM. Inputs to the CHRM were received from the AH-1 Cobra Project Management office (PMO), Army aviation maintenance facilities, fielded AH-1F Cobra units, and Korean Air Lines (KAL). Government furnished information (GFI) and contractor furnished information (CFI) from KAL were received in a fairly timely manner. Total integration of all AH-1F Cobra Rewire Program acquisitions efforts was beyond the scope of the delivery order. DTIC

IMPLEMENTATION AND DEMONSTRATION OF A MULTIPLE MODEL ADAPTIVE ESTIMATION FAILURE DETECTION SYSTEM FOR THE F-16 M.S. Thesis
Peter K. Eide Dec. 1994 215 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289301; AFIT/GE/ENG/94D-06) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A Multiple Model Adaptive Estimation (MMAE) algorithm is implemented with the fully nonlinear six-degree-of-motion, Simulation Rapid-Prototyping Facility (SRF) VISTA F-16 software simulation tool. The algorithm is demonstrated to be capable of identifying flight critical aircraft actuator and sensor failures at a low dynamic pressure (20,000 ft, .4 Mach). Research included single and dual complete failures. Tuning methods for accommodating model mismatch, including addition of discrete dynamics pseudonoise and continuous measurement pseudonoise, are discussed and demonstrated. Scalar residuals within each filter are also examined and characterized for possible use as an additional failure declaration voter. Robustness to sensor failures provided by MMAE-based control is also demonstrated. An investigation of algorithm performance off the nominal design conditions is accomplished as a first step towards full flight envelope coverage. The algorithm is composed of a bank of Kalman filters modeled to match particular hypotheses of the real world. Each presumes a single failure in one of the flight critical actuators (left/right stabilators, left/right flaperon, rudder), or sensors (forward velocity, angle of attack, pitch rate, normal acceleration, roll rate, yaw rate, and lateral acceleration), and one presumes no failure. For dual failures, a hierarchical structure is used to keep the number of on-line filters to a minimum. This research advances the technology by testing algorithm performance against the most complete simulation model currently available. DTIC

THE LIFT-FAN AIRCRAFT: LESSONS LEARNED
Wallace H. Deckert Mar. 1995 64 p
(Contract NAS2-5364)
(NASA-CR-196694; A-95041; NAS 1.26:196694) Avail: CASI HC A04/MF A01

This report summarizes the highlights and results of a workshop held at NASA Ames Research Center in October 1992. The objective of the workshop was a thorough review of the lessons learned from past research on lift fans, and lift-fan aircraft, models, designs, and components. The scope included conceptual design studies, wind tunnel investigations, propulsion systems components, piloted simulation, flight of aircraft such as the SV-5A and SV-5B and a recent lift-fan aircraft development project. The report includes a brief summary of five technical presentations that addressed the subject The Lift-Fan Aircraft: Lessons Learned. Author

SAILPLANE GLIDE PERFORMANCE AND CONTROL USING FIXED AND ARTICULATING WINGLETS M.S. Thesis
James David Colling May 1995 100 p
(Grant NAG1-1522)
(NASA-CR-198579; NAS 1.26:198579) Avail: CASI HC A05/MF A02

An experimental study was conducted to investigate the effects of controllable articulating winglets on glide performance and yawing moments of high performance sailplanes. Testing was conducted in the Texas A&M University 7 x 10 foot Low Speed Wind Tunnel using a full-scale model of the outboard 5.6 feet of a 15 meter class high performance sailplane wing. Different wing tip configurations could be easily mounted to the wing model. A winglet was designed in which the cant and toe angles as well as a rudder on the winglet could be adjusted to a range of positions. Cant angles used in the investigation consisted of 5, 25, and 40 degrees measured from the vertical axis. Toe-out angles ranged from 0 to 22.5 degrees. A rudder on the winglet was used to study the effects of changing the camber of the winglet airfoil on wing performance and wing yawing moments. Rudder deflections consisted of-10, 0, and 10 degrees. Test results for a fixed geometry winglet and a standard wing tip are presented to show the general behavior of winglets on sailplane wings, and the effects of boundary-layer turbulators on the winglets are also presented. By tripping the laminar boundary-layer to turbulent before laminar separation occurs, the wing performance was increased at low Reynolds numbers. The effects on the lift and drag, yawing moment, pitching moment, and wing root bending moment of the model are presented. Oil flows were used on the wing model with the fixed geometry winglet and the standard wing tip to visualize flow directions and areas of boundary layer transition. A cant angle of 25 degrees and a toe-out angle of 2.5 degrees provided an optimal increase in wing performance for the cant and toe angles tested. Maximum performance was obtained when the winglet rudder remained in the neutral position of zero degrees. By varying the cant, toe, and rudder angles from their optimized positions, wing performance decreases. Although the winglet rudder proved to be more effective in increasing the yawing moment compared to varying the cant and toe angles, the amount of increased yawing moment was insignificant when compared to that produced by the vertical tail. A rudder on the winglet was determined to be ineffective for providing additional yaw control. Author

GEOPHEX AIRBORNE UNMANNED SURVEY SYSTEM
I. J. Won and D. W. A. Taylor 1995 13 p Presented at the Opportunity 95: Environmental Technology Through Small Business, Morgantown, WV, 16-17 Nov. 1994
(Contract DE-AR21-93MC-30358)
(DE95-007566; DOE/MC-30358/95/C0432; CONF-9411149-4) Avail: CASI HC A03/MF A01

The purpose of this effort is to design, construct, and evaluate a portable, remotely-piloted, airborne, geophysical survey system. This nonintrusive system will provide 'stand-off' capability to conduct surveys and detect buried objects, structures, and conditions of interest at hazardous locations. This system permits two operators to rapidly conduct geophysical characterization of hazardous environmental sites. During a survey, the operators remain remote from, but within visual distance, of, the site. The sensor system never contacts the Earth, but can be positioned near the ground so that weak anomalies can be detected. DOE

The AGARD Structures and Materials Panel held a specialists' Meeting to address composite repair of military aircraft. The meeting focused on two main areas, repair of metal structures using composite patches and repair of composite structures using composite or metal patches. The work presented had direct application to the maintenance and support of military aircraft. Repair of military aircraft provides both a means to extend the useful life of the airframe beyond the original design life and a method to maintain military readiness by returning damaged aircraft to service. For individual titles, see N95-27505 through N95-27528.

BONDED COMPOSITE REPAIR OF METALLIC AIRCRAFT COMPONENTS: OVERVIEW OF AUSTRALIAN ACTIVITIES

A. A. Baker *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 14 p (For primary document see N95-27504 09-05)
Copyright Avail: CASI HC A03/MF A03

After first providing an overview of the status of Australian applications of bonded composite repairs to metallic aircraft structure (mainly based on boron/epoxy composites) the problems in certifying composite repairs to critical cracks in primary metallic structure are discussed. The development of acceptable generic certification procedures is essential if the use of this efficient cost-effective repair technology is to be widely employed in military and civil aircraft. One requirement for certification is the ability to predict the fatigue-crack growth behavior in patched components. An approach to developing this capability is described, based on Rose's model to estimate stress intensity in patched panels. The model is extended to allow for disbonding damage in the patch system. Experimental results are presented to demonstrate the validity of this approach for boron/epoxy-FM73 repairs to aluminum alloy 2024T3. Author

Bonded boron/epoxy doublers are an alternative method vs. riveted doublers for repair and reinforcement of metallic aircraft structures. The boron/epoxy doublers provide cost and/or performance advantages for many applications. Today over 4,500 are flying on military aircraft, mostly in Australia and the U.S.A., and the use is increasing. Commercial aircraft, which are also aging, are beginning to use this technology, with about 50 boron doublers flying for flight evaluation since 1989 (plus about another 100 since the mid 1970s in France). This paper summarizes the major uses of boron/epoxy doublers, focusing on recent and current U.S. applications (other papers at this Meeting describe activities in Australia, Canada, and France). These include a 1993 report summarizing the successful use on the wing pivot of over 400 F-111s for 20 years (no disbonds have been noted); fleetwide installations on the B-1 and C-141 (over 1800 doublers); and flight testing on F-16, T-38, C-130 and KC-135 aircraft. Commercially there have been successful flight evaluations on 2 Fed Ex 747s and the Lycoming ALF 502 engine cowl on 2 BAE 146s. A Service Bulletin has been issued for retrofit of over 1200 cowls for the latter. This paper also summarizes the installation process (which is very viable), and describes two recent technical advances in chemically preparing aluminum surfaces for bonding of boron/epoxy doublers. This paper also presents the results of an extensive test program sponsored by Textron at Boeing of 110 ultimate tensile strength and 143 fatigue tests of boron/epoxy doublers bonded to 7075-T6 aluminum with simulated cracks. ADHESIVELY BONDED COMPOSITE PATCH REPAIR OF CRACKED ALUMINUM ALLOY STRUCTURES

P. Poole, A. Young, and A. S. Ball (British Aerospace Defence Ltd., Farnborough, England.) *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 12 p (For primary document see N95-27504 09-05)
Copyright Avail: CASI HC A03/MF A03

Research at the Defence Research Agency (DRA) on adhesively bonded composite patch repair of fatigue cracked aluminum alloy structures is reviewed briefly. Theoretical and experimental results are reported which indicate the effectiveness of such repairs in terms of the reductions in stress intensity factor due to patching. The influence of warm-moist environments on the long-term performance of bonded patches is considered, and the advantages and disadvantages of using carbon fiber reinforced plastic (CFRP) patches, rather than boron fiber reinforced plastic (BFRP) patches, are discussed. An investigation by British Aerospace of the feasibility of using bonded composite patches to repair cracked primary aircraft structures is summarized. For the range of applications investigated, bonded composite patch repairs are shown to offer potential savings of 60-75 percent, compared to conventional repair methods. The current position regarding in-service trials is summarized, with no evidence of crack growth after 990 flying hours. Author

COMPOSITE REPAIR OF METALLIC AIRFRAME: TWENTY YEARS OF EXPERIENCE [REPARATIONS COMPOSITES DE STRUCTURES METALLIQUES: VINGT ANS D'EXPERIENCE]

Micheline Druet *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 8 p In FRENCH (For primary document see N95-27504 09-05)
Copyright Avail: CASI HC A02/MF A03

During the 70's, the availability of unidirectional boron fiber fabric at Dassault Aviation did allow reinforcement of metallic structures by direct ply lay up on the metal. To be able to apply these reinforcement on airplanes, it was necessary to define a resin system inducing low thermal stresses in the metal during its cure, and with acceptable mechanical properties after aging. Validation was done by simple tests on samples, by complex test with simultaneous thermal and mechanical cycling, and application of test repairs on the major fatigue test of the Mercure airplane. Reinforcements of that type are in service for almost 20 years on the Mercure airliner. Author

BONDED COMPOSITE REPAIR OF THIN METALLIC MATERIALS: VARIABLE LOAD AMPLITUDE AND TEMPERATURE CYCLING EFFECTS

M. D. Raizenne, T. J. Benak, J. B. R. Heath, D. L. Simpson, and A. A. Baker (Defence Science and Technology Organisation, Melbourne, Australia.) *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 12 p Original contains color illustrations (For primary document see N95-27504 09-05)
Copyright Avail: CASI HC A03/MF A03

An investigation into the effectiveness of bonded boron/epoxy composite patch repairs on edge notched Al 2024-T3 sheets has been completed. Testing was carried out under variable amplitude load and temperature cycling. Nine sandwich type specimens were precracked of which eight were repaired using bonded precured unidirectional boron fiber reinforced epoxy patches. Three structural adhesive systems were evaluated, two thermally activated epoxies, FM73 and FM300, and a room temperature cure acrylic, Versilok 201. The variable amplitude load sequence used was FALSTAFF, a typical fighter aircraft loading spectrum. The temperature profile was derived from F/A-18 usage data. Temperatures varied between -35 C and +80 C with a one in eight temperature cycle occurrence of +108 C. The effect of moisture absorption in the adhesive and the matrix was also investigated. Bonded patches on three specimens were preconditioned to a moisture weight gain of 1.5 percent prior to testing. The data generated compares specimen fatigue crack growth rates between the three adhesives for three environments: room temperature, temperature cycled and temperature cycled with moisture preconditioning. DESIGN AND STRUCTURAL VALIDATION OF CF116 UPPER WING SKIN BORON DOUBLER

J. Smith *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 11 p (For primary document see N95-27504 09-05)
Copyright Avail: CASI HC A03/MF A03

Cracks were found around fastener holes in the critical area known as the 'Golden Triangle' on the upper wing skin of several CF116 aircraft. To restore the structural integrity of the wing, cracks around these fastener holes are removed and interference fit steel bushings are installed. A boron-epoxy doubler is then bonded over the reworked area to reduce stress levels. The doubler is viewed as a fatigue enhancement device and not as a repair to a cracked skin. An analytical methodology is used to assess the bond line integrity and the load transfer in the doubler. A 49% reduction of stress level is predicted by the bonded joint analytical approach. A finite element analysis reveals that a 47% stress reduction is expected in the exterior surface of the wing skin, while a 37% reduction in the interior surface is predicted. Based on a strain survey performed following the installation of a doubler on the CF116 full scale fatigue test, it is shown that analytical predictions agree with experimental results. Author

STRUCTURAL MODIFICATION AND REPAIR OF C-130 WING STRUCTURE USING BONDED COMPOSITES

J. Grosko *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 9 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A02/MF A03

Lockheed Aeronautical Systems Company (LASC) -- in a program sponsored by the United States Air Force, Warner Robins Air Logistics Center, C-130 Directorate -- has developed concepts wherein bonded high-modulus composite materials can be applied to structurally repair or enhance the wing box of C-130 aircraft. Two separate approaches are taken. In the first, boron/epoxy reinforcing strips are applied to wing box lower surface structure to relieve high stress at a particular location in the wing surface panel. This modification is ideally used on undamaged structure to prevent wing surface cracking. In the second approach, graphite reinforced patches are applied in the same vicinity to arrest crack growth. Both concepts were successfully demonstrated on opposite sides of a full-scale wing test article. Design details, the materials and processes, the methods of installation and the measured effectiveness of both the boron/epoxy strips and the graphite/epoxy patches are discussed. Author (revised)

Reinforcement of aircraft components by patching is never completely effective because of improper bonding or damage of the reinforcement in service. There is always the uncertainty for evaluating the remaining strength or life of a repaired structure. Developed in this work is a methodology for evaluating the reinforcement effectiveness by considering two basic types of partially damaged patches; they are referred to as collinear and transverse debonding with respect to the crack plane. The former refers to debonding over a region ahead of only one of the crack tips where the load and geometry are symmetric across the crack plane, while the latter is concerned with debonding over a region to the side of the crack where symmetry is no longer preserved across the crack plane. Finite elements are employed to obtain the stresses and strains from which the strain energy densities can be determined for analyzing the failure behavior of the patched panels. The local and global maximum of the minimum strain energy density function, designated by((dW/dV)(sup max, sub min))(sub L) at L and ((dW/DV)(sup max, sub min)(sub G) at G, are found and applied to define failure instability. The distance ell between L and G serves as a measure of crack instability; it increases with the debonded area. That is, debonding tends to enhance failure instability by fracture initiating from the existing crack. For approximately the same area of debonding, crack initiation for collinear debonding would be more unstable as compared with transverse debonding for loads directed normal to the crack. Introduced also is a Patch Effectiveness Index (PEI) that serves as a measure of the load carrying capacity of the damaged patch. In this case, transverse debonding is more detrimental than collinear debonding because a more significant reduction in the load transfer path occurs in the former case. In general, both ell and PEI would have to be considered for assessing the integrity of the damaged patch. Author

The Navy is unique in that a portion of the maintenance actions performed on operational aircraft must be accomplished on board ship or in remote field locations. Historically, Navy driven composite repair programs have addressed materials and concepts specifically directed at accomplishing repairs in the fleet operating environment. This paper discusses recent developments in the area of composite repair materials for the application of bonded patches to honeycomb and complex shaped monolithic composite structure. A two part adhesive that meets the storage and processing requirements for field repair applications was evaluated for use in repair of honeycomb structure. Low temperature adhesive processing and honeycomb compatibility tests were investigated. In another effort, wet lay-up repair resins and processes were characterized for repair of highly curved composite structure. The materials and equipment used in the study are fully compatible with field repair requirements. Composite repair materials for application of bonded patches to honeycomb and complex shaped monolithic composite structure are described. Low temperature adhesive processing development for bonding composite patches to moisturized structure is described. Cure temperatures as low as 90 C were used for curing a two part ambient storable adhesive. Mechanical properties and thermal stability of the cured adhesive is reported using a number of cycles. In another effort wet lay-up repair resins and processes were characterized which allow for the fabrication of fully inspectable wet lay-up patches. The materials and equipment are fully compatible with field repair requirements. Laminate mechanical properties and resin storage stability were characterized and reported. Author

A considerably large four point bending test box was available simulating the curved integrally stiffened CFC fuselage skin of a fighter aircraft. This box was used for a skin repair trial with subsequent testing. The repair was performed in the environment of an external test laboratory, i.e. abroad of the original shop or maintenance facilities. 'On Aircraft' conditions have been simulated with all the referring access, tooling and quality assurance difficulties. The repaired test box demonstrated during static testing, loading the repair in tension, compression and shear, that the applied repair procedure is feasible to be applied on CFC structures. The repair procedure and the subsequent testing will be presented and the results will be discussed. Author

RAPID REPAIR OF LARGE AREA DAMAGE TO CONTOURED AIRCRAFT STRUCTURES

James A. Frailey and Douglas W. Carter (Wright Lab., Wright-Patterson AFB, OH.) *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 9 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A02/MF A03

In a program sponsored by Air Force Wright Laboratory (WL/FIVST), Lockheed Fort Worth Company has developed field-level procedures for repair of large area damage to highly contoured aircraft structures. The combination of aircraft structures designed with enhanced survivability and the utilization of larger and more powerful ballistic threats have resulted in the requirement to develop new, creative approaches for rapid repair of large area structural damage. Furthermore, current aircraft design employing advanced composite materials on highly contoured surfaces increases the challenge of implementing workable battle damage repairs. This paper details the development of an advanced battle damage repair concept designed to repair damage up to approximately 15 inches in diameter on highly contoured surfaces. It employs a quick, reusable tooling mold that replicates the contour of the damaged aircraft for the purpose of processing a composite patch. Several one year room temperature storable, thermoset, composite systems were examined for processability, handleability and mechanical performance to determine their suitability as repair patch materials. The most promising were further tested and demonstrated in a large scale validation test. Author

COMPOSITE REPAIR OF A CF18: VERTICAL STABILIZER LEADING EDGE

A. E. Maier and G. Guenther *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 16 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A03/MF A03

This paper describes the engineering and manufacturing procedures that were applied in a repair task of a CF18 Vertical Stabilizer Leading Edge, made out of CFC honeycomb structure with multiple in-service impact damages in an aerodynamic sensitive area of the fin. 'On-aircraft' damage assessment, manufacturing of a relatively thin contoured CFC doubler, replacement of metal honeycomb core and finally quality assurance and strength verification procedures of the repair are described to restore full design strength of the component and the operational aircraft capability. This paper addresses three separate composite repair issues currently being investigated at the Defence Research Establishment Pacific (DREP) in support of Canada's CF-18 aircraft. First, the problem of skin/core debonding that can occur during elevated temperature bonded repairs of honeycomb sandwich structure is discussed and the results of tests which help to quantify the role played by bondline degradation are presented. Next, the final development phase of an on-going effort to establish a reliable and effective means of repairing delamination damage is reported. In particular, the design of a resin injection device and a series of tests to evaluate its performance are described. Finally, a battle damage repair issue, namely the advantages and disadvantages of cleaning up the damaged composite material found around entry and exit holes created by live fire, is discussed. Test data is presented which compares the different consequences under tensile and compression loading. Author

REPAIR TECHNOLOGY FOR THERMOPLASTIC AIRCRAFT STRUCTURES

M. W. Heimerdinger et al *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 12 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A03/MF A03

The Flight Dynamics and Materials Directorates of the U.S. Air Force Wright Aeronautical Laboratories jointly sponsored a program for 'Repair Technology for Thermoplastic Aircraft Structures' (REPTAS) performed by Northrop Corporation, Aircraft Division. In the program Northrop developed, validated and demonstrated on-aircraft repair design concepts and processes for field repair of advanced thermoplastic structures. The REPTAS program was accomplished through the performance of a 48-month effort comprising three phases. Phase 1 assessed field level repair facilities and technology that are currently available and identified their applicability to repair thermoplastic (TP) structures. A baseline aircraft structure was selected to validate the selected repair process. Currently available thermoplastic materials were reviewed and materials selected for evaluation. In the selection process the objective was to select one semicrystalline, one amorphous, and one pseudo-thermoplastic material. APC-2 was evaluated as the baseline material for the process development efforts. Novel processing techniques were investigated for the repair procedures. Phase 2 developed the selected technologies for the on-aircraft repair of TP structures at a coupon and subelement level. Design concepts were developed that are compatible with field level capabilities and restore structural integrity to the aircraft. In the process of developing a bonding procedure using polyetheretherketone (PEEK) as the bonding film, it became apparent that the required bonding temperature of 385 C (725 F) created internal thermal stresses in the base structure and resulted in unacceptable delaminations. As an alternative, an investigation of amorphous bonding was included which demonstrated its feasibility for TP repair. In Phase 3 a full-scale advanced thermoplastic composite structural component was selected and used as a demonstration article for the selected design concept. Derived from text

REPAIR OF HIGH TEMPERATURE COMPOSITE AIRCRAFT STRUCTURE

Jerome J. Connolly *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 12 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A03/MF A03

This paper describes the final portion of a high temperature composite repair development program sponsored by Wright Patterson Materials Directorate. Initially, BMI adhesives and prepregs were selected based on their compatibility with in-service repair cure scenarios. These typically involve curing in a non-autoclave environment using vacuum consolidation only. The selected material systems were then used to develop a comprehensive repair procedure for highly curved aircraft structure. Once developed, the procedure was then applied to a curved structure representative of a flight surface leading edge. Baseline and repair specimens were fabricated and tested in compression at both room temperature dry and elevated temperature dry conditions. The results of these test validated the repair procedure. EXTERNAL PATCH REPAIR OF CFRP/HONEYCOMB SANDWICH

K. Wolf and R. Schindler *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 11 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A03/MF A03

This paper addresses the repair of impact-damaged honeycomb sandwich structures with thin skins made of carbon fiber reinforced plastic (CFRP). An experimental study concerned with evaluating several types of bonded external patch repairs is presented. The evaluation included cocured as well as precured patch techniques utilizing advanced repair materials. Three repair schemes were applied to honeycomb sandwich manufactured from 125 C as well as 175 C curing carbon fiber reinforced fabric prepregs. The effectiveness of the repairs was examined through a series of static and fatigue compression tests. Based on the mechanical test results and a comparison of the repair procedures it was found that the bonded precured patch concept is the most suitable approach for repairing impact-damaged sandwich structures under field-level maintenance limitations. SCARF REPAIRS TO GRAPHITE/EPOXY COMPONENTS

A. A. Baker, R. J. Chester, G. R. Hugo, and T. C. Radtke *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 12 p (For primary document see N95-27504 09-05)

Significant damage to graphite/epoxy laminates up to 16 plies in thickness is often repaired with a bonded external patch. This type of repair is well suited to honeycomb panels and is relatively easy to apply even under field conditions. Thicker laminates generally carry too much load for external patch repairs and so either bolted patches or scarf repairs are generally used. Scarf repairs exhibit a nominally uniform shear stress distribution within the joint and have the advantage of low peel stress due to the lack of eccentricity in the load path. Scarf repairs are, however, difficult to produce, may involve the removal of a significant amount of parent material, and the uniform shear stresses may make the joint susceptible to creep failure. An experimental program was undertaken to determine the strain capacity of a scarf repair to a 21 ply laminate. The aim of the program is to demonstrate a strain capability in the repair of at least 5200 microstrain when tested under hot/wet conditions. Although some of the specimens tested have achieved this strain level, the performance of the current scarf joint is marginal under these conditions. Detailed analysis of this joint shows that high stresses arise from ply drop-offs within the repair doubler and at the ends of the scarf taper. Good correlation has been observed between the results from the Finite-Element models and those from experimental specimens, indicating that the models are a useful tool to assist in the design of joints of this type. SCARF JOINT TECHNIQUE WITH COCURED AND PRECURED PATCHES FOR COMPOSITE REPAIR

F. Elaldi, S. Lee (Institute for Aerospace Research, Ottawa, Ontario.), and R. F. Scott (Institute for Aerospace Research, Ottawa, Ontario.) *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 12 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A03/MF A03

The scarf joint technique is one of the latest techniques used for repairing composite aircraft structures. This paper describes scarf joints comprised of vacuum and autoclave precured and cocured fiber glass epoxy patches bonded to autoclave and vacuum precured parent fiber glass epoxy laminates. Autoclave and vacuum cured parent laminates and the scarf joints were prepared and exposed to the same temperature and moisture environment for comparison. All specimens were loaded in tension at three temperatures. Interlaminar shear strength (ILSS) tests were also carried out for the parent materials. As expected, the tensile strength and ILSS decrease when the material has been exposed to moisture and tested at elevated temperature. No significant difference was reported for either tensile strength or ILSS between autoclave and vacuum cured materials. The room temperature repair efficiencies are reported for single scarf repairs comprised of vacuum cocured and precured patches. These repair efficiencies were found to be similar to the efficiency of the autoclave precured patch repair. This result supports the feasibility of scarf joint repairs in base level facilities. COMPOSITE OR METALLIC BOLTED REPAIRS ON SELF-STIFFENED CARBON WING PANEL OF THE COMMUTER ATR72 DESIGN CRITERIA, ANALYSIS, VERIFICATION BY TEST

A. Tropis *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 21 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A03/MF A03

The introduction into service, in 1989, of ATR72 with an outer wing in carbon led Aerospatiale to develop primary structure repair processes which fulfill Airworthiness requirements and which could be performed by the airlines in typical maintenance conditions. This paper describes the two types of bolted repairs developed within the scope of the wing certification: composite doubler or metallic doubler. An analytical microcomputer calculation program allows the critical area and the strength capability of the repaired panel to be determined. This program is validated by tests. Author

DAMAGE OCCURRENCE ON COMPOSITES DURING TESTING AND FLEET SERVICE: REPAIR OF AIRBUS AIRCRAFT

G. Stemmer *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 8 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A02/MF A03

The application of composite materials to civil aircraft structure was growing during the past 25 years with every new aircraft which went into service. With these materials in commercial use it became necessary to define repairs in the case the component becomes damaged. During fatigue testing at component level the limits for allowable damage and maximum repair sizes were determined for standard damage events and manufacturing defects. The values are depending on structural design, material behavior and local strains or stresses. For simple damages on regular structures necessary repair actions are defined in the Structural Repair Manual. With an approved inspection philosophy the structure is under observation during airline service. It will be presented how the repair philosophy within Airbus Industrie partner companies is defined and which damages were reported on aircraft already in service. Some examples should explain the lessons we have learned from those failures occurred during component testing and airline service. Author

REPAIRS OF CFC PRIMARY STRUCTURES

H. GarciaNunez, A. BarrioCardaba, and A. Franganillo *In* AGARD, Composite Repair of Military Aircraft Structures Jan. 1995 10 p (For primary document see N95-27504 09-05)

Copyright Avail: CASI HC A02/MF A03

The use of composites in the last decades has been mainly restricted to secondary structures, with repair methods well known to the airlines. In today's aircraft, a significant amount of primary structure is designed and built in high strength composite materials. Repairs for these elements must take into consideration the restoration of structural strength and stiffness, still being easy to be applied by aircraft operators, with a minimum of special facilities, and requiring a minimum of aircraft-on-ground time. A large number of important structural elements in CFC now in service have been designed and manufactured by CASA. This paper describes how composite repairs are dealt with at CASA, starting from the design board, and the analyses and tests carried out to demonstrate compliance with certification requirements. The RAAF has used bonded composite patches for structural repairs to aircraft for nearly twenty years, and they are now seen as a reliable alternative to mechanically fastened repairs. To control the implementation of the repair technology, RAAF propose to adopt Engineering Standard C5033 on Composite Materials and Adhesive Bonded Repairs. The Standard addresses repair authorization and design, as well as repair methodology and quality control. This paper will describe the philosophy of repair design contained in the standard, and outline the materials and process controls necessary for performance of repairs which comply with ISO 9001. AEROELASTICITY AND STRUCTURAL OPTIMIZATION OF COMPOSITE HELICOPTER ROTOR BLADES WITH SWEPT TIPS

K. A. Yuan and P. P. Friedmann Hampton, VA NASA May 1995 433 p

(Grant NAG1-833; RTOP 505-63-36-06)

(NASA-CR-4665; NAS 1.26:4665) Avail: CASI HC A19/MF A04

This report describes the development of an aeroelastic analysis capability for composite helicopter rotor blades with straight and swept tips, and its application to the simulation of helicopter vibration reduction through structural optimization. A new aeroelastic model is developed in this study which is suitable for composite rotor blades with swept tips in hover and in forward flight. The hingeless blade is modeled by beam type finite elements. A single finite element is used to model the swept tip. Arbitrary cross-sectional shape, generally anisotropic material behavior, transverse shears and out-of-plane warping are included in the blade model. The nonlinear equations of motion, derived using Hamilton's principle, are based on a moderate deflection theory. Composite blade cross-sectbnal properties are calculated by a separate linear, two-dimensional cross section analysis. The aerodynamic loads are obtained from quasi-steady, incompressible aerodynamics, based on an implicit formulation. The trim and steady state blade aeroelastic response are solved in a fully coupled manner. In forward flight, where the blade equations of motion are periodic, the coupled trim-aeroelastic response solution is obtained from the harmonic balance method. Subsequently, the periodic system is linearized about the steady state response, and its stability is determined from Floquet theory. Author

Fatigue crack growth under stationary Gaussian random loading is considered. A specially developed computerized testing system and software are used for generation of the random loading and investigation of crack growth. The sliding summation numerical method was used for generation of a random loading history characterized by a given autocorrelation function. As far as the loading history of a sufficient length is generated a sequence of maxima and minima is extracted and arranged with the predetermined frequency. The next Operation is elimination of the small amplitude cycles in accordance with the predetermined threshold value and. determination of the minima and maxima two-dimensional distribution of the edited process. A specially built transition matrix derived from this distribution was used for the real-time generation of the random loading during the test. Experimental investigation of the developed random loading generation procedure and crack growth process was performed using aluminium alloy multicrack panel type specimens providing possibility of observation of an array of simultaneously growing cracks. Dependence of fatigue crack life time on random loading parameters as well as stochastic characteristics of crack growth were studied. DTIC

(AD-A291628) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Unmanned Aerial Vehicles (UAV) Joint Project Office was officially established in response to Congressional direction by a charter signed by the Director of Defense Research and Engineering on 16 October 1989. This 1994 UAV Master Plan is the sixth submission to Congress. It provides the acquisition and technology strategies, management, and program plans for nonlethal UAV's. Lethal UAV's are addressed in the classified Department of Defense Standoff Weapons Master Plan. This Master Plan is structured into three parts: an Executive Summary, a main body of 10 sections providing extensive detail, and an appendix of supporting material including discussions of dual uses of UAV's and UAV civil airspace management issues. TIE-DOWN TRIALS INVOLVING A SIKORSKY S-70B-2 HELICOPTER

Jeremy Blackwell Jan. 1995 40 p Original contains color illustrations

(DSTO-TR-0132; AR-008-418) Copyright Avail: Issuing Activity

Two tie-down trials involving a Sikorsky S-70B-2 helicopter are outlined. The first was land-based and utilized a hydraulic tilt table. The second took place on board an FFG-7 frigate. The trials are part of a DSTO (Defense Science and Technology Organization) investigation aimed at improving the tie-down procedures of S-70 B-2 helicopters when operating from ships. A preliminary analysis of the data is presented and indicates that the type of lashing used to secure the helicopter can have a significant effect on the loads transmitted to the fuselage as well as affecting the relative motion of the aircraft. The effect of aircraft brakes on or off was examined and found to result in noticeable differences to the aircraft behavior. During the ship trial, one type of tie-down lashing was observed to suffer from significant slippage through its locking mechanism. Author

NUMERICAL SIMULATION OF CRACK GROWTH IN PRESSURIZED FUSELAGES Ph.D. Thesis
H. A. J. Knops 26 Sep. 1994 208 p
(PB95-192415; ISBN-90-9007413-9) Avail: CASI HC A10/MF A03

The main objective of the present research is to develop a number of tools for the numerical simulation of crack behavior in pressurized fuselages. In these calculations the geometrically nonlinear effects described above and the influence of stiffening components on the crack behavior will be taken into account. Since the flapping phenomenon that is observed in experiments on pressurized aircraft fuselages with initially longitudinal cracks is not yet well understood, a major goal of the present research is to simulate crack flapping numerically and to predict whether a crack will flap and at what crack length. In real structures there will always be a plastic zone around the crack tip. However, the behavior of such 'real' cracks is still believed to be dictated by a number of linear elastic crack tip parameters. Therefore in our research we will assume that linear-elastic fracture mechanics conditions hold and that the state of stress around the crack tip is characterized by these linear-elastic crack tip parameters. PARTIAL DISCHARGE TESTING OF HIGH VOLTAGE WIRING HARNESS FOR AIRBORNE DISPLAYS Final Report, 15 Dec. 1993 - 15 Feb. 1994
Gregory L. Rhoads, John Horwath, and Daniel Schweickart Oct. 1994 18 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289150; WL-TR-94-2099) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The pilots of advanced tactical airplanes must evaluate increasingly more information. Innovations such as the heads-up display were designed to decrease the visual workload. More flexible helmet-mounted CRT's are now being developed, presenting new design challenges. For example, high voltage leads for helmet-mounted displays must incorporate a quick release, load-break mechanism into the wiring harness to accommodate pilot ejection. The potential presence of flammable vapors resulted in an arc-suppressing, quick-disconnect connector design which opens the high voltage via hermetically sealed contacts. The sealed contacts contain any arcing and break the circuit before the connector separates. The prototype harness routes two 13.5 kilovolt rated direct current leads along with other wiring via the quick-disconnect connector. The high voltage and compact design motivate concerns about partial discharge degradation of the insulation, particularly at sub-atmospheric pressures. The harness has been tested for partial discharges at simulated altitudes up to 70,000 feet in the Aerospace Power Division's High Power Laboratory. DTIC

OPERATOR MODELING IN COMMERICAL AVIATION: COGNITIVE MODELS, INTELLIGENT DISPLAYS, AND PILOT'S ASSISTANTS Final Report, 1 Jul. 1990 - 30 Apr. 1994
T. Govindaraj and C. M. Mitchell 30 Apr. 1994 22 p
(Contract NCC2-675)
(NASA-CR-198609; NAS 1.26:198609) Avail: CASI HC A03/MF A01

One of the goals of the National Aviation Safety/Automation program is to address the issue of human-centered automation in the cockpit. Human-centered automation is automation that, in the cockpit, enhances or assists the crew rather than replacing them. The Georgia Tech research program focused on this general theme, with emphasis on designing a computer-based pilot's assistant, intelligent (i.e, context-sensitive) displays, and an intelligent tutoring system for understanding and operating the autoflight system. In particular, the aids and displays were designed to enhance the crew's situational awareness of the current state of the automated flight systems and to assist the crew's situational awareness of the current state of the automated flight systems and to assist the crew in coordinating the autoflight system resources. The activities of this grant included: (1) an OFMspert to understand pilot navigation activities in a 727 class aircraft; (2) an extension of OFMspert to understand mode control in a glass cockpit, Georgia Tech Crew Activity Tracking System (GT-CATS); (3) the design of a training system to teach pilots about the vertical navigation portion of the flight management system -VNAV Tutor; and (4) a proof-of-concept display, using existing display technology, to facilitate mode awareness, particularly in situations in which controlled flight into terrain (CFIT) is a potential. LIFE CYCLE COSTS OF ALTERNATIVES FOR F-16 PRINTED CIRCUIT BOARD DIAGNOSIS EQUIPMENT M.S. Thesis
Kent R. Montgomery and Clifford B. Thorstenson Dec. 1994 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288744; AFIT/GSS/LAR/94D-3) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study analyzes two alternatives for printed circuit board (PCB) diagnosis for the F-16 depot PCB repair shop from a life cycle cost (LCC) perspective. Alternative 1 assumes the use of the current F-16 automatic test equipment (ATE) while Alternative 2 augments the current ATE with infrared imaging test equipment. Infrared imaging is a developed technology that is currently available to the Air Force in a commercial-off-the-shelf (COTS) form. Using the Cost Analysis and Strategy Assessment (CASA) Life Cycle Cost (LCC) Model and data from the DL41 database on F-16 PCB's this study determined that over the current expected life of the F-16, the next twenty-five years, a savings of approximately $1.1 million (1994 dollars) can be realized by augmenting the current F-16 ATE with infrared imaging test equipment 15% of the F-16 printed circuit boards (PCB's) are single card PCB's which can be tested using infrared imaging test. This study assumes that the total number of PCB's and the percentage of single card PCB's does not change over the F-16's lifetime. Sensitivity analyses are performed varying the percentage of single card PCB's, the total number of PCB's and the F-16 lifetime to determine the effects these changes might have on the total life cycle cost of Alternative 2. SIMULATION MODEL OF THE INTEGRATED FLIGHT/PROPULSION CONTROL SYSTEM, DISPLAYS, AND PROPULSION SYSTEM FOR ASTOVL LIFT-FAN AIRCRAFT

W. Y. William Chung, Paul F. Borchers, and James A. Franklin Apr. 1995 50 p
(RTOP 505-68-32)
(NASA-TM-108866; A-950048; NAS 1.15:108866) Avail: CASI HC A03/MF A01

A simulation model has been developed for use in piloted evaluations of takeoff, transition, hover, and landing characteristics of an advanced, short takeoff, vertical landing lift fan fighter aircraft. The flight/propulsion control system includes modes for several response types which are coupled to the aircraft's aerodynamic and propulsion system effectors through a control selector tailored to the lift fan propulsion system. Head-up display modes for approach and hover, tailored to their corresponding control modes are provided in the simulation. Propulsion system components modeled include a remote lift and a lift/cruise engine. Their static performance and dynamic response are represented by the model. A separate report describes the subsonic, power-off aerodynamics and jet induced aerodynamics in hover and forward flight, including ground effects. Author

CHARACTERISTICS OF THE TURBINE INLET TEMPERATURE SENSING CIRCUIT FOR THE T56 TURBO-PROP ENGINE

K. F. Fraser Nov. 1994 57 p
(DSTO-TR-0095; AR-008-374) Copyright Avail: Issuing Activity (DSTO, Melbourne Victoria, Australia)

The temperature to voltage transfer characteristics of the standard turbine inlet temperature averaging sensor for the T56 turbo-prop engine are derived using measured resistance parameters for the 18-thermocouple network. The transfer characteristics of an add-on individual thermocouple temperature sensing circuit are also derived and some of the requirements of the associated signal conditioning circuit are briefly reviewed. EXPERIMENT ON A RECTANGULAR CROSS SECTION SCRAMJET COMBUSTOR. 2: EFFECTS OF FUEL INJECTOR GEOMETRY

Atsuo Murakami, Tomoyuki Komuro, and Kenji Kudou Dec. 1993 27 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1220) Avail: CASI HC A03/MF A01

An experimental study of a rectangular cross section scramjet combustor was carried out. The effects on mixing and combustion performances of the rearward-facing steps, fuel injection orifice arrangements and the length of the constant height section downstream of the step were examined. The peak wall pressure, namely the strength of the precombustion shock, increased as the length of the constant height section downstream of the injection orifices increased. The injected fuel jets coalesced if the precombustion shock was too strong, while they stratified if it was too weak. Hence the mixing and combustion efficiencies of these two cases were low. To achieve better fuel mixing, the length of the constant height section must be selected so that it gives the most suitable strength of the precombustion shock. Sweep of the rearward-facing steps and the orifice arrangements had little effect on the mixing and combustion efficiencies. Author

EFFECTS OF DUST FROM STORAGE HEATERS ON IGNITION IN SCRAMJETS

Apr. 1994 20 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1234) Avail: CASI HC A03/MF A01

The effect of dust on ignition delay in ground-testing of scramjet engines was investigated analytically. Incandescent particles issued from a storage air heater cause premature ignition of H2 - fuel injected into the combustor. In order to prevent erroneous experimental results, the concentration of particles greater than about 40 microns in size must be restricted to less than 10(exp 3) particles/m(exp 3). The thermal and chemical inhibition effects due to fine particles can be neglected in engine testing, if the mass fraction of dust in the heated air is less than 10(exp -1) in the wind tunnel. This analysis is applicable to the mechanism of powdered flame suppressants. Author

TURBOMACHINERY DESIGN AND TONAL ACOUSTICS COMPUTATIONS Final Report, Jun. 1993 - Jan. 1995

Akil A. Rangwalla Jan. 1995 53 p Original contains color illustrations
(Contract NCC2-767)
(NASA-CR-197749; NAS 1.26:197749; MCAT-95-17) Avail: CASI HC A04/MF A01; 2 functional color pages

The objective of this research was two-fold. The first objective was to complete the three-dimensional unsteady calculations of the flow through a new transonic turbine and study the effects of secondary flows due to the hub and casing, tip clearance vortices, and the inherent three-dimensional mixing of the flow. It should be noted that this turbine was and is still in the design phase and the results of the calculations have formed an integral part of the design process. The second objective of this proposal was to evaluate the capability of rotor-stator interaction codes to calculate tonal acoustics. Derived from text

STALL PRECURSOR STUDY OF HIGH FREQUENCY DATA FOR THREE HIGH SPEED, SWEPT COMPRESSOR ROTORS M.S. Thesis

James F. Anderton Dec. 1994 165 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289379; AFIT/GAE/ENY/94D-13) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The frequency spectra of three single stage, high speed compressor rotors were derived and analyzed from experimental data. The compressor rotors included straight, backward-swept, and forward-swept blade designs. Data was acquired from four pressure transducers located on the compressor casing and arranged axially between locations 40% of blade chord upstream of the rotor face to just over the leading edge of the blades. Each rotor was throttled to stall at two constant speeds between 90% and 100% of design speed. Data digitization at 20 kHz revealed multiples of the rotor frequency up to and beyond a dominant blade passing frequency. Further analyses for characteristics of impending stall included examination of integrated signal power and cross-correlations of transducer signals from the upstream and downstream-most pressure transducers. Results of the integrated signal power approach showed promise as a potential pre-stall warning. This technique detected differences in the signal power at the two transducers in the immediate pre-stall time frame. Pre-stall warning times varied from several seconds to less than 0.5 second, with higher rotor speeds giving less warning time. Results for the forward-swept rotor, however, showed that integrated signal power did not warn of impending stall, and that surge energies played an important role in this rotor's stalling characteristics. An hypothesis for the behavior of the forward swept rotor, based on the possibility of stall development beginning in the near-hub radial region of this compressor, was developed. DTIC

OPTIMIZATION OF WAVE ROTORS FOR USE AS GAS TURBINE ENGINE TOPPING CYCLES
Jack Wilson (NYMA, Inc., Brook Park, OH.) and Daniel E. Paxson Jun. 1995 11 p Presented at the 1995 Aerospace Atlantic Conference and Exposition, Dayton, OH, 23-25 May 1995; sponsored by SAE
(Contract NAS3-27186; RTOP 505-90-58)
(NASA-TM-106951; E-9689; NAS 1.15:106951) Avail: CASI HC A03/MF A01

Use of a wave rotor as a topping cycle for a gas turbine engine can improve specific power and reduce specific fuel consumption. Maximum improvement requires the wave rotor to be optimized for best performance at the mass flow of the engine. The optimization is a trade-off between losses due to friction and passage opening time, and rotational effects. An experimentally validated, one-dimensional CFD code, which includes these effects, has been used to calculate wave rotor performance, and find the optimum configuration. The technique is described, and results given for wave rotors sized for engines with sea level mass flows of 4, 26, and 400 lb/sec. Author

PROPULSION SYSTEM ASSESSMENT FOR VERY HIGH UAV UNDER ERAST Final Report
James L. Bettner, Craig S. Blandford, and Bernie J. Rezy Cleveland, OH NASA May 1995 156 p
(Contract NAS3-25950; RTOP 537-10-20)
(NASA-CR-195469; E-9653; NAS 1.26:195469; EDR-17199) Avail: CASI HC A08/MF A02

A series of propulsion systems were configured to power a sensor platform to very high altitudes under the Experimental Research Advanced Sensor Technology (ERAST) program. The unmanned aircraft was required to carry a 100 kg instrument package to 90,000 ft altitude, collect samples and make scientific measurements for 4 hr, and then return to base. A performance screening evaluation of 11 propulsion systems for this high altitude mission was conducted. Engine configurations ranged from turboprop, spark ignition, two- and four-stroke diesel, rotary, and fuel cell concepts. Turbo and non-turbo-compounded, recuperated and nonrecuperated arrangements, along with regular JP and hydrogen fuels were interrogated. Each configuration was carried through a preliminary design where all turbomachinery, heat exchangers, and engine core concepts were sized and weighed for near-optimum design point performance. Mission analysis, which sized the aircraft for each of the propulsion systems investigated, was conducted. From the array of configurations investigated, the propulsion system for each of three different technology levels (i.e., state of the art, near term, and far term) that was best suited for this very high altitude mission was identified and recommended for further study. PERFORMANCE STUDY FOR INLET INSTALLATIONS
Donald C. Bingaman Nov. 1992 94 p
(Contract NAS1-19462; RTOP 505-68-70-06)
(NASA-CR-189714; NAS 1.26:189714) Avail: CASI HC A05/MF A01

A conceptual design trade study was conducted by McDonnell Aircraft Company (MCAIR) and NASA LARC PAB to determine the impact of inlet design features incorporated for reduced detectability on inlet performance, weight, and cost, for both fighter and attack-type aircraft. Quality Function Deployment (QFD) techniques were used to prioritize trade study issues, and select 'best' air induction system configurations for each of two notional aircraft, the Multi-Role Fighter (MRF) and the Advanced Medium Attack (AMA) bomber. Database deficiencies discovered in the trade study process were identified, and technology roadmaps were developed to address these deficiencies. Finally, two high speed inlet wind tunnel model concepts were developed for follow-on wind tunnel investigations. Author

EXPERIMENTAL INVESTIGATION OF INLET-COMBUSTOR ISOLATORS FOR A DUAL-MODE SCRAMJET AT A MACH NUMBER OF 4
Saied Emami (Lockheed Engineering and Sciences Co., Hampton, VA.), Carl A. Trexler, Aaron H. Auslender (Lockheed Engineering and Sciences Co., Hampton, VA.), and John P. Weidner May 1995 93 p
(RTOP 505-70-62-01)
(NASA-TP-3502; L-17422; NAS 1.60:3502) Avail: CASI HC A05/MF A01

This report details experimentally derived operational characteristics of numerous two-dimensional planar inlet-combustor isolator configurations at a Mach number of 4. Variations in geometry included (1) inlet cowl length; (2) inlet cowl rotation angle; (3) isolator length; and (4) utilization of a rearward-facing isolator step. To obtain inlet-isolator maximum pressure-rise data relevant to ramjet-engine combustion operation, configurations were mechanically back pressured. Results demonstrated that the combined inlet-isolator maximum back-pressure capability increases as a function of isolator length and contraction ratio, and that the initiation of unstart is nearly independent of inlet cowl length, inlet cowl contraction ratio, and mass capture. Additionally, data are presented quantifying the initiation of inlet unstarts and the corresponding unstart pressure levels. Author

NUMERICAL ANALYSIS OF INTRA-CAVITY AND POWER-STREAM FLOW INTERACTION IN MULTIPLE GAS-TURBINE DISK-CAVITIES
M. M. Athavale (CFD Research Corp., Huntsville, AL.), A. J. Przekwas (CFD Research Corp., Huntsville, AL.), R. C. Hendricks, and B. M. Steinetz May 1995 19 p Presented at the Turbo Expo 1995, Houston, TX, 5-8 Jun. 1995; sponsored by ASME
(RTOP 242-50-01)
(NASA-TM-106886; E-9523; NAS 1.15:106886) Avail: CASI HC A03/MF A01

A numerical analysis methodology and solutions of the interaction between the power stream and multiply-connected multi-cavity sealed secondary flow fields are presented. Flow solutions for a multi-cavity experimental rig were computed and compared with experimental data of Daniels and Johnson. The flow solutions illustrate the complex coupling between the main-path and the cavity flows as well as outline the flow thread that exists throughout the subplatform multiple cavities and seals. The analysis also shows that the de-coupled solutions on single cavities is inadequate. The present results show trends similar to the T-700 engine data that suggests the changes in the CDP seal altered the flow fields throughout the engine and affected the engine performance. Author

Ceramic matrix composite fabrication by microwave assisted chemical vapor infiltration (MWCVI) has been demonstrated as a feasible, faster, and more economical technique as compared to conventional CVI. Two deposition systems, carbon and silicon carbide, were investigated using this processing technique. Densification rates over an order of magnitude higher have been achieved on small cylindrical Nicalon fiber preforms. Economic forecasts based on previous SiC deposition and this Phase 1 work shows a significant improvement in part cost as compared to conventional CVI work. A reduction in cost of a factor of 20 has been calculated. A larger, commercial microwave system has been designed for scaled up prototype part fabrication. DTIC

In the late twentieth century, ecological problems have become essential to the development of civilization on Earth and affect not only ecologists but everyone. The electrical power industry has made a substantial contribution to the destruction of the natural environment and therefore electrical engineers are particularly obliged to repair the damage and to make the least amount of harm as possible. For a long time some electromagnetic devices and processes have been known and applied to clean the air and water and to replace those more noxious to the environment. Recently, low temperature plasma has been especially used as developed applications to treat water, sewage, air and toxic gases. Ozone synthesis and toxic gas neutralization are carried out by means of electric methods in electromagnetic devices. DTIC

DESIGN AND SYNTHESIS OF A REAL-TIME CONTROLLER FOR AN UNMANNED AIR VEHICLE M.S. Thesis
Peter M. Hoffman Sep. 1994 121 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289134) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Naval Postgraduate School is developing a vertical take-off and landing (VTOL) unmanned air vehicle (UAV) that can transition to horizontal flight, once airborne, in order to take advantage of the improvements in speed, range, and loiter time that horizontal, fixed-wing flight provides. This research investigates the design requirements of the central controlling device for that UAV, including the specific problems of defining the necessary hardware components and developing software for executive control. First, hardware requirements needed to be determined. By exploring the general operational requirements of the UAV and taking into account space and weight limitations, a hardware suite was selected which could provide adequate functionality to replace the human traits of a pilot. In order to provide 'awareness' of the operational environment, motion sensors, navigation equipment, and communication equipment was required. Controllable servo-motors were necessary to move control surfaces appropriately. Computer hardware, necessary to provide system intelligence, was selected in order to inter-operate with the other hardware. Next, a Real-Time Executive (RTE) software program was designed to provide the functionality and coordination of all hardware components. Device drivers for each component were developed, and overall coordination was planned using a Yourdon style essential model. Periodic interrupts were used to control execution time. Last, the specifications and configuration of all hardware components were completely documented, and the operation of the RTE program fully explained. From this understanding of the overall control system, future development can continue, resulting in a more effective and efficient UAV design. DTIC

(RTOP 505-59-36)
(NASA-TM-110349; A-950055; NAS 1.15:110349; USAATCOM-TR-95-A-003) Avail: CASI HC A06/MF A02

An extensive investigation of the effects of pitch-roll coupling on helicopter handling qualities was performed by the U.S. Army and Deutsche Forschungsanstalt fur Luft- und Raumfahrt (DLR), using a NASA ground-based and a DLR in-flight simulator. Over 90 different coupling configurations were evaluated using a high gain roll-axis tracking task. The results show that although the current ADS-33C coupling criterion discriminates against those types of coupling typical of conventionally controlled helicopters, it is not always suited for the prediction of handling qualities of helicopters with modern control systems. Based on the observation that high frequency inputs during tracking are used to alleviate coupling, a frequency domain pitch-roll coupling criterion that uses the average coupling ratio between the bandwidth and neutral stability frequency is formulated. This criterion provides a more comprehensive coverage with respect to the different types of coupling, shows excellent consistency, and has the additional benefit that compliance testing data are obtained from the bandwidth/phase delay tests, so that no additional flight testing is needed. ELECTRO-HYDROSTATIC ACTUATOR CONTROLLER DESIGN USING QUANTITATIVE FEEDBACK THEORY M.S. Thesis
Ki Ho Kang Dec. 1994 111 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289220; AFIT/GE/ENG/94D-18) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Electro-Hydrostatic Actuator (EHA) technology offers a higher degree of combat survivability and easier maintainability of the aircraft flight control system, because all the components necessary to operate the actuator are collocated with the actuator. Quantitative Feedback Theory (QFT) is used to design a control system for the EHA. The impact of parameter variations, sensor noise, and flight conditions are explicitly considered in the design process. The solution utilizes a two loop QFT feedback structure. The inner loop structure stabilizes the motor's angular velocity and decreases the outer loop's uncertainty. The outer loop structure controls the RAM piston's position to track the input command. The resulting design is not only robust with respect to plant parameter variations, but is also insensitive to the effects of sensor noise. The actuator's phase lag is reduced by incorporating phase constraints in the QFT design paradigm. QFT is shown to be a viable tool in solving a real-world problem. DTIC

An aircraft's response to control inputs varies widely throughout its flight envelope. The aircraft configuration also impacts control response through variations in center of gravity and moments of inertia. Designing a flight control system (FCS) to accommodate the full flight envelope and configuration set of an aircraft is clearly a complex undertaking. Quantitative feedback theory (QFT) is a design tool which enables the engineer to attack this task in an efficient way. Although QFT is a robust control design technique, it is an interactive algorithm allowing the engineer full control over compensator order and gain. In this research effort, a full subsonic flight envelope FCS is designed for the VISTA F-16 aircraft using QFT. Four aircraft configurations are considered. The strict control of the compensator order and gain allowed by QFT facilitates the attainment of desired performance while avoiding physical saturations. In addition, flying qualities are imbedded in the longitudinal design through the use of a control parameter which varies with the aircraft's energy state. This parameter is synthesized to closely reflect the actual control desires of the pilot throughout the aircraft flight envelope. Linear simulations with realistically large control inputs are used to validate the design. DTIC

ADVANCED FORMATION FLIGHT CONTROL M.S. Thesis

Michael J. Veth Dec. 1994 145 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289271; AFIT/GE/ENG/94D-30) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In this thesis, the formation flight control problem is continued from four previous theses. Automatic formation flight involves controlling multiple aircraft equipped with standard Mach-hold, altitude hold, and heading-hold autopilots to maintain a desired distance from a lead aircraft or 'rabbit'. Changes in the rabbit's states are treated as disturbances to the system and rejected. Previous research is advanced in the following areas: Higher-order aircraft/autopilot models are included into the design and a new feedback control law is employed, resulting in more accurate simulations. An energy tracking scheme is developed and is shown to reduce wing aircraft energy excursions. Finally, the formation hold autopilot is modified to allow the wing aircraft to orbit a stationary reference point on the earth at a desired range, airspeed, and altitude. The importance of the disturbance rejection capability of the controller is demonstrated through comparisons of linearized model predictions with nonlinear simulations. The design tradeoffs between performance and robustness are emphasized. DTIC

FLIGHT CONTROL DESIGN USING MIXED H2/MICRON OPTIMIZATION M.S. Thesis

Douglas D. Decker Dec. 1994 159 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289288; AFIT/GA/ENY/94D-8) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis examines the use of the mixed H2/Microns optimal control synthesis method in the design of a flight control system for the lateral/directional axes of the F-16 Variable Stability In-Flight Simulator Test Aircraft (VISTA). The method is designed to minimize the H2 norm (two-norm) for a given value of microns. This should provide adequate noise and disturbance rejection while maintaining robustness against several types of uncertainties in the system. This thesis finds that, for this problem, the two-norm is not an accurate representation of the outputs of interest. When the two-norm is broken up into its constituent parts an appropriate solution can be found. This thesis also finds that it is possible to use an H2 controller which is destabilizing to the evaluation model as the starting point in the mixed H2/IL curve and still get an acceptable answer. A numerical approach was used, utilizing a recently improved computer algorithm. DTIC

MODELING OF AIRCRAFT UNSTEADY AERODYNAMIC CHARACTERISTICS. PART 2: PARAMETERS ESTIMATED FROM WIND TUNNEL DATA

Vladislav Klein (Joint Inst. for Advancement of Flight Sciences, Hampton, VA.) and Keith D. Noderer (Joint Inst. for Advancement of Flight Sciences, Hampton, VA.) Apr. 1995 43 p
(RTOP 505-64-52-01)
(NASA-TM-110161; NAS 1.15:110161) Avail: CASI HC A03/MF A01

Aerodynamic equations with unsteady effects were formulated for an aircraft in one-degree-of-freedom, small-amplitude, harmonic motion. These equations were used as a model for aerodynamic parameter estimation from wind tunnel oscillatory data. The estimation algorithm was based on nonlinear least squares and was applied in three examples to the oscillatory data in pitch and roll of 70 deg triangular wing and an X-31 model, and in-sideslip oscillatory data of the High Incidence Research Model 2 (HIRM 2). All three examples indicated that a model using a simple indicial function can explain unsteady effects observed in measured data. The accuracy of the estimated parameters and model verification were strongly influenced by the number of data points with respect to the number of unknown parameters. Author

DEVELOPMENT OF A TECS CONTROL-LAW FOR THE LATERAL DIRECTIONAL AXIS OF THE MCDONNELL DOUGLAS F-15 EAGLE M.S. Thesis

Michael A. Bruzzini Dec. 1994 114 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289771; AFIT/CI/CIA/94-159) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this report is to develop automatic aircraft flight control systems using the concept of Total Energy Control System (TECS) in the lateral directional axis for the McDonnell Douglas F-15 Eagle. Nonlinear simulation was originally developed from actual flight tests conducted by the U.S. Air Force and generated into a Fortran code. Lt James P. Dutton then took the flight data code and generated a SIMULINK file 10. Using the SIMULINK file a control law developed on the linearized model can then be tested on the nonlinear model. DTIC

DESIGN AND DEVELOPMENT OF A TEST RIG FOR THE HIGH FREQUENCY TESTING OF ROLLING SLEEVE AIRSPRINGS

G. Swanton Feb. 1995 32 p Original contains color illustrations
(DSTO-TN-0001; AR-009-201) Copyright Avail: Issuing Activity

AMRL's F/A-18 IFOSTP fatigue test has introduced several new concepts in the field of aircraft structural testing. One of the innovations has been the development of the pneumatic actuator or 'rolling sleeve' airspring for the application of aircraft maneuver loads. These airsprings have been subjected to several preliminary acceptance test phases, one of which simulated the effects of high frequency buffet loads. This report details the design and implementation of the test rig developed to conduct this type of testing. Author

THE VALUE OF SIMULATION FOR TRAINING Final Report, Sep. 1993 - Apr. 1994

Jesse Orlansky, Carl J. Dahlman, Colin P. Hammon, John Metzko, Henry L. Taylor, and Christine Youngblut Sep. 1994 173 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289174; IDA-P-2982; IDA/HQ-94-45529; SBI-AD-E501-856) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

All types of simulation are considered: (1) stand-alone; (2) networked interactive simulation; (3) live exercises; and (4) combat models. The utility of simulation is examined for individual and collective training conducted at institutions and in operational units. Cost data are reported on individual training at schools, training technology, collective training in units, operating tempo, and procurement of simulation. Simulators used for flight training and maintenance training are cost-effective, compared to the use of actual equipment; the same is true for computer-based instruction. The acceptance and use of simulators depends heavily on the existence of adequate training programs, adequate performance feed-back, ability to replicate actual operating conditions, and user acceptance by unit commanders. Distributed interactive simulation is expected to make a major improvement in collective and joint training but it is too early to assess its utility. Suggestions are made with regard to the development of cost data needed for establishing policy on the use of simulation for training as well as for the support of technology needed to improve collective and joint training and joint readiness. EXTENSION TO THE DYNAMIC MODELING OF THE LARGE ANGLE MAGNETIC SUSPENSION TEST FIXTURE M.S. Thesis - Old Dominion Univ., May 1995 Progress Report, 1 Nov. 1994 - 30 Apr. 1995

Lucas E. Foster and Colin P. Britcher May 1995 133 p

(Grant NAG1-1056)

(NASA-CR-197801; NAS 1.26:197801) Avail: CASI HC A07/MF A02

The Large Angle Magnetic Suspension Test Fixture (LAMSTF) is a laboratory scale proof-of-concept system. The configuration is unique in that the electromagnets are mounted in a circular planar array. A mathematical model of the system had previously been developed, but was shown to have inaccuracies. These inaccuracies showed up in the step responses. Eddy currents were found to be the major cause of the modeling errors. In the original system, eddy currents existed in the aluminum baseplate, iron cores, and the sensor support frame. An attempt to include the eddy current dynamics in the system model is presented. The dynamics of a dummy sensor ring were added to the system. Adding the eddy current dynamics to the simulation improves the way it compares to the actual experiment. Also presented is a new method of determining the yaw angle of the suspended element. From the coil currents the yaw angle can be determined and the controller can be updated to suspend at the new current. This method has been used to demonstrate a 360 degree yaw angle rotation. This final report covers the work done on corporate agreement NCC2-616 over a period of 5 1/2 years. It is broken into three segments of approximately 1 1/2 to 2 years each. The report is a summary report and is not intended to be comprehensive of all the work done under this corporate agreement. A more complete coverage of the work done is obtained from the papers and reports listed in the 'Papers' section. Additional reporting of significant work was done through 'Technical Highlights' and 'Research and Technical Summaries'. A listing of copies are given in the 'Technical Highlights and R and T' section. The work was also reported in a series of seminars, conference meetings, branch reviews, workshops, and project reviews. A list of these talks is given in the 'Presentation' section. Also during this time three students ranging from high school to graduate level were supervised. A list of the students and the type of work accomplished is given in the 'Mentoring' section. The report concludes with the 'Appendices' sections which include the three papers produced during the last 1 1/2 years of this corporate agreement. Author

PHOTOACOUSTIC CHAMBERS FOR STUDYING SOLIDS AND GASES: THEORY AND PRACTICAL EXAMPLES [KOMORY FOTOAKUSTYCZNE DO BADANIA CIAL STALYCH I GAZOW: TEORIA I PROZYKLADY ROZWIAZAN]

Jerzy Motylewski and Tomasz Zmierczak 1994 34 p In POLISH

(ISSN 0208-5658)

(IFTR-39/1994) Avail: Issuing Activity (Polish Academy of Sciences, Warsaw, Poland)

In this article the authors describe examples of theoretical models of the operation of photoacoustic chambers designed to operate in photoacoustic spectroscopic systems used to analyze the physical and chemical properties of solids and gases by means of photoacoustic spectroscopy (PAS). In particular, the theoretical analysis covers the effect of the chamber's dimensions, the analyzed sample, and the modulation of the exciting light on the amplitude of the photoacoustic signal and the ways in which energy losses in the photoacoustic detector are accounted for. The authors note the possibility of reducing the effect of penetrating acoustic noise in chambers used to analyze the properties of gases by using acoustic filters. The authors describe examples of photoacoustic chambers designed to analyze solids and gases. Transl. by SCITRAN

AN INVESTIGATION OF THE AFIT 2-INCH SHOCK TUBE AS A FLOW SOURCE FOR SUPERSONIC TESTING M.S. Thesis

Kevin M. Vlcek Dec. 1994 52 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289246; AFIT/GA/ENY/94D-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An investigation of the AFIT high pressure shock tube was conducted to determine how closely it followed ideal shock tube theory and to determine the available test times for an attached Mach 3 nozzle. The driver section was five feet (1.52 m) long and the driven section was 25 feet (7.62 m) long. The driver gas used for this study was helium while the driven gas was atmospheric air. The pressure rise measured behind the incident shock wave was, on average, 30% lower than predicted by the ideal shock tube relations. Behind the reflected shock, the pressure rise was 65% lower than predictions based on initial driver gas pressure. Due to supply pressure limits and lower than predicted pressures behind the shock waves, fully expanded flow in the Mach 3 nozzle was not attained. However, steady overexpanded flows of Mach 2.74-2.96 were observed for periods of 4-12 milliseconds. DTIC

NASA LEWIS RESEARCH CENTER'S COMBUSTOR TEST FACILITIES AND CAPABILITIES

Jean Bianco May 1995 13 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; cosponsored by AIAA, ASME, SAE, and ASEE

(RTOP 505-62-82)

(NASA-TM-106903; E-9599; NAS 1.15:106903; AIAA Paper 95-2681)

Avail: CASI HC A03/MF A01

NASA Lewis Research Center (LeRC) presently accommodates a total of six combustor test facilities with unique capabilities. The facilities are used to evaluate combustor and afterburner concepts for future engine applications, and also to test the survivability and performance of innovative high temperature materials, new instrumentation, and engine components in a realistic jet engine environment. The facilities provide a variety of test section interfaces and lengths to allow for flametube, sector and component testing. The facilities can accommodate a wide range of operating conditions due to differing capabilities in the following areas: inlet air pressure, temperature, and flow; fuel flow rate, pressure, and fuel storage capacity; maximum combustion zone temperature; cooling water flow rate and pressure; types of exhaust - atmospheric or altitude; air heater supply pressure; and types of air heaters - vitiated or nonvitiated. All of the facilities have provisions for standard gas (emissions) analysis, and a few of the facilities are equipped with specialized gas analysis equipment, smoke and particle size measurement devices, and a variety of laser systems. This report will present some of the unique features of each of the high temperature/high pressure combustor test facilities at NASA LeRC. Author

SUBSURFACE RADAR INVESTIGATIONS AT THE PEGASUS GLACIAL-ICE RUNWAY AND WILLIAMS FIELD, MCMURDO STATION, ANTARCTICA
Steven A. Arcone, Allan J. Delaney, and Wayne Tobiasson Nov. 1994 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant NSF DPP-87-20063; DA Proj. 4A1-61102-AT-24)
(AD-A289323; CRREL-94-12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Subsurface radar was used to profile ice and snow conditions on the Ross Ice Shelf at McMurdo Station, Antarctica, during mid-January 1993. Deconvolution and migration were often used to improve vertical resolution and spatial imaging. Profiles at a pulse center frequency of 400 MHz along the 3.2-km-long Pegasus ice runway show many low-density horizons above 9 m depth that are up to 30 m long. They are associated with air bubbles included during refreezing of meltwater and are interpreted as layers between a few and tens of centimeters thick. There is a strong reflecting horizon at about 9 m depth that is probably from brine intrusion as it is continuous with the intrusion into the snow to the east. Diffraction asymptotes give a dielectric constant near 3.2 for material above the brine level, a value that implies near-solid ice. Profiles at 100 MHz along the road between Pegasus runway and Williams Field in the accumulation zone show snow features such as layer deformation and intrusive brine layers that both abruptly and gradually change in depth. A single profile at a relic solid waste dump at Williams Field detected buried debris and ice within the upper 7 m. A survey of a suspected fuel spill shows some local disturbances near the center, but no excavation was done to verify the findings. Profiles traversing the sewage sumps at Williams Field outline the extent of the sewage deposition, and give depths to contaminated snow that closely agree with observation. Despite variability in dielectric properties, single-layer migration effectively improves the resolution of subsurface conditions. Recommendations are made for future surveys. DTIC

A METHODOLOGY TO ASSESS THE UTILITY OF FUTURE SPACE SYSTEMS M.S. Thesis
Bruce Rayno Dec. 1994 89 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289414; AFIT/GSO/ENS/94D-14) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research identifies the assumptions and simplifications in the SPACECAST 2020 value model and assesses modifications. The model determines and prioritizes future space systems' utility toward controlling and exploiting space. This study shows that the assumption of using an additive utility function is valid. This research shows that the mission areas are mutually utility independent allowing the use of the multiplicative utility function. This research also uses the multilinear function, which requires utility independence implied in mutual utility independence. This study makes modifications to the 98 SPACECAST 2020 measure of merit scoring functions. These scoring functions all used the same scoring scale and they do not allow for the determination of the overall current capability toward controlling and exploiting space. Most of these functions are replaced with either a concave, convex, linear, or 'S' scoring function, which has an expanded capability range to include current and future capabilities. The modified scoring functions and alternate utility functions do not alter the SPACECAST 2020 results but do improve upon the model. This study also presents a flexible but formalized method of space system concept identification, which explicitly considers space operational requirements. DTIC

(GAO/NSIAD-95-141BR; B-260888) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20884-6015 HC

This report is a result of an investigation into NASA's April 1994 estimated cost of $475 million for a Titan 4-Centaur launch of the Cassini spacecraft. The goal of the investigation was to determine the extent to which cost saving opportunities exist. The Air Force agreement to provide NASA with an expendable launch vehicle for this project prompted the analyses of Air Force as well as NASA documents, including memoranda of agreement, estimated and negotiated costs, funding and budget data, the mission integration contract, and launch and production schedules. Since the initial call to investigate, the cost estimate has been reduced by NASA to $452 million, principally because a reduction of the estimate of mission integration costs. The investigation determined a further reduction in overall cost may be possible because NASA completed its negotiation of the mission integration contract for $15 million less than estimated. However, cost savings in other areas of the Cassini launch are unlikely, and some of NASA's costs could increase. A briefing section details these findings. CASI

MISSION TO PLANET EARTH. STRATEGIC ENTERPRISE PLAN, 1995-2000
May 1995 52 p
(NASA-TM-110620; NAS 1.15:110620) Avail: CASI HC A04/MF A01

Mission to Planet Earth (MTPE) provides long-term understanding of the earth system needed to protect and improve our environment, now and for future generations. This MTPE Strategic Enterprise Plan states how NASA intends to meet its responsibility to the Nation for developing a long-term, integrated program of environmental observation in support of informed decision-making. This plan implements the NASA Strategic Plan for the MTPE Enterprise; it is the first version of a rolling 5-year plan that will be updated annually. It is consistent with the interagency program developed by the Committee on Environment and Natural Resources of the National Science and Technology Council and implemented in large part through the U.S. Global Change Research Program. This report consists of the following sections: (1) introduction; (2) scientific foundation; (3) mission (destination and purposes); (4) principle of operation (ethical and quality assurance standards); (5) customer base (to ensure that the right products and services are delivered); (6) internal and external assessments; (7) assumptions; (8) goals, objectives, and strategies; (9) linkages to other strategic enterprises; and (10) summary. MARS SAMPLE RETURN MISSION UTILIZING IN-SITU PROPELLANT PRODUCTION Final Report
Robert Zubrin and Steve Price 31 Mar. 1995 69 p Original contains color illustrations
(Contract NAS9-19359)
(NASA-CR-188371; NAS 1.26:1988371; MCR-95-557) Avail: CASI HC A04/MF A01; 7 functional color pages

This report presents the results of a study examining the potential of in-situ propellant production (ISPP) on Mars to aid in achieving a low cost Mars Sample Return (MSR) mission. Two versions of such a mission were examined: a baseline version employing a dual string spacecraft, and a light weight version employing single string architecture with selective redundancy. Both systems employed light weight avionics currently being developed by Lockheed Martin, Jet Propulsion Lab and elsewhere in the aerospace community, both used a new concept for a simple, light weight parachuteless sample return capsule, both used a slightly modified version of the Mars Surveyor lander currently under development at Lockheed Martin for flight in 1998, and both used a combination of the Sabatier-electrolysis and reverse water gas shift ISPP systems to produce methane/oxygen propellant on Mars by combining a small quantity of imported hydrogen with the Martian CO2 atmosphere. It was found that the baseline mission could be launched on a Delta 7925 and return a 0.5 kg sample with 82 percent mission launch margin;over and beyond subsystem allocated contingency masses . The lightweight version could be launched on a Mid-Lite vehicle and return a 0.25 kg sample with 11 percent launch margin, over and above subsystem contingency mass allocations. Author

COMPUTING NORAD MEAN ORBITAL ELEMENTS FROM A STATE VECTOR M.S. Thesis
Dwight E. Andersen Dec. 1994 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289281; AFIT/GSO/ENS/94D-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

NORAD maintains and disseminates mean orbital elements on Earth-orbiting satellites in the form of Two-Line Element Sets (TLE). Five mathematical propagator models were developed for NORAD's use to predict the position and velocity using TLE's. This study investigated two approaches, Newton's method and direct iteration, to inverting this process by iterating to obtain NORAD-compatible mean orbital elements from a position and velocity state vector and the drag term. The Newton's iteration method was developed but not tested. The less computationally intensive direct iteration method was developed, coded in FORTRAN, and tested. The initial guess and subsequent corrections in the iterative process used the osculating elements computed from the state. The results showed the computation of the osculating elements to be unstable for low-Earth orbits with low eccentricity and moderate inclination, never converging to a solution for those cases. The scope of this research was limited to using two of the five propagators: Simplified General Perturbation Version 4 (SGP4) for low Earth orbits and SDP4 for deep space orbits. DTIC

WEIGHTING SCHEME FOR THE SPACE SURVEILLANCE NETWORK AUTOMATED TASKER M.S. Thesis
Beth L. Petrick Dec. 1994 96 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289285; AFIT/GSO/ENS/94D-13) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this research is to find the best weighting scheme in the SPADOC 4C Sensor Tasking Prototype. This software, known as the Prototype Tasker, assigns a tasking to each sensor of the Space Surveillance Network. A tasking is a list of objects in which the sensor needs to gather positional data, called observations. One of the inputs to the Prototype Tasker is a user-definable weighting scheme. The goal is to find the weighting scheme that produces the most efficient taskings. This problem was solved using a Simulated Annealing algorithm. The values in the weighting scheme were the variables of the problem. The objective function was a measure of the goodness of each tasking produced. The Simulated Annealing algorithm was set to vary the weighting scheme and find the one that produces the tasking with the highest objective function. There were four successful executions of the simulated annealing algorithm. Each one produced a different weighting scheme. However, there were noticeable trends in the relative magnitudes of the weights. Also, it was noticed that a slight decrease in the number of observations on the taskings will increase the expected amount of information gathered by the Space Surveillance Network. DTIC

This conference publication includes 41 papers and abstracts presented at the Flight Mechanics/ Estimation Theory Symposium on May 16-18, 1995. Sponsored by the Flight Dynamics Division of Goddard Space Flight Center, this symposium featured technical papers on a wide range of issues related to orbit-attitude prediction, determination, and control; attitude sensor calibration; attitude determination error analysis; attitude dynamics; and orbit decay and maneuver strategy. Government, industry, and the academic community participated in the preparation and presentation of these papers. For individual titles, see N95-27764 through N95-27804.

Avail: CASI HC A03/MF A04

This paper examines filter tuning techniques for a sequential orbit determination (OD) covariance analysis. Recently, there has been a renewed interest in sequential OD, primarily due to the successful flight qualification of the Tracking and Data Relay Satellite System (TDRSS) Onboard Navigation System (TONS) using Doppler data extracted onboard the Extreme Ultraviolet Explorer (EUVE) spacecraft. TONS computes highly accurate orbit solutions onboard the spacecraft in realtime using a sequential filter. As the result of the successful TONS-EUVE flight qualification experiment, the Earth Observing System (EOS) AM-1 Project has selected TONS as the prime navigation system. In addition, sequential OD methods can be used successfully for ground OD. Whether data are processed onboard or on the ground, a sequential OD procedure is generally favored over a batch technique when a realtime automated OD system is desired. Recently, OD covariance analyses were performed for the TONS-EUVE and TONS-EOS missions using the sequential processing options of the Orbit Determination Error Analysis System (ODEAS). ODEAS is the primary covariance analysis system used by the Goddard Space Flight Center (GSFC) Flight Dynamics Division (FDD). The results of these analyses revealed a high sensitivity of the OD solutions to the state process noise filter tuning parameters. The covariance analysis results show that the state estimate error contributions from measurement-related error sources, especially those due to the random noise and satellite-to-satellite ionospheric refraction correction errors, increase rapidly as the state process noise increases. These results prompted an in-depth investigation of the role of the filter tuning parameters in sequential OD covariance analysis. This paper analyzes how the spacecraft state estimate errors due to dynamic and measurement-related error sources are affected by the process noise level used. This information is then used to establish guidelines for determining optimal filter tuning parameters in a given sequential OD scenario for both covariance analysis and actual OD. Comparisons are also made with corresponding definitive OD results available from the TONS-EUVE analysis. Author

EVALUATION AND MODELING OF AUTONOMOUS ATTITUDE THRUST CONTROL FOR THE GEOSTATION OPERATIONAL ENVIRONMENTAL SATELLITE (GOES)-8 ORBIT DETERMINATION
W. Forcey (Computer Sciences Corp., Lanham, MD.), C. R. Minnie (Computer Sciences Corp., Lanham, MD.), and R. L. DeFazio *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 17-29 (For primary document see N95-27763 09-13)
(Contract NAS5-31500)
Avail: CASI HC A03/MF A04

The Geostationary Operational Environmental Satellite (GOES)-8 experienced a series of orbital perturbations from autonomous attitude control thrusting before perigee raising maneuvers. These perturbations influenced differential correction orbital state solutions determined by the Goddard Space Flight Center (GSFC) Goddard Trajectory Determination System (GTDS). The maneuvers induced significant variations in the converged state vector for solutions using increasingly longer tracking data spans. These solutions were used for planning perigee maneuvers as well as initial estimates for orbit solutions used to evaluate the effectiveness of the perigee raising maneuvers. This paper discusses models for the incorporation of attitude thrust effects into the orbit determination process. Results from definitive attitude solutions are modeled as impulsive thrusts in orbit determination solutions created for GOES-8 mission support. Due to the attitude orientation of GOES-8, analysis results are presented that attempt to absorb the effects of attitude thrusting by including a solution for the coefficient of reflectivity, C(R). Models to represent the attitude maneuvers are tested against orbit determination solutions generated during real-time support of the GOES-8 mission. The modeling techniques discussed in this investigation offer benefits to the remaining missions in the GOES NEXT series. Similar missions with large autonomous attitude control thrusting, such as the Solar and Heliospheric Observatory (SOHO) spacecraft and the INTELSAT series, may also benefit from these results. DIFFERENCED RANGE VERSUS INTEGRATED DOPPLER (DRVID) IONOSPHERIC ANALYSIS OF METRIC TRACKING IN THE TRACKING AND DATA RELAY SATELLITE SYSTEM (TDRSS)

M. S. Radomski (Computer Sciences Corp., Lanham, MD.) and C. E. Doll *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 31-45 (For primary document see N95-27763 09-13)
(Contract NAS5-31500)
Avail: CASI HC A03/MF A04

The Differenced Range (DR) Versus Integrated Doppler (ID) (DRVID) method exploits the opposition of high-frequency signal versus phase retardation by plasma media to obtain information about the plasma's corruption of simultaneous range and Doppler spacecraft tracking measurements. Thus, DR Plus ID (DRPID) is an observable independent of plasma refraction, while actual DRVID (DR minus ID) measures the time variation of the path electron content independently of spacecraft motion. The DRVID principle has been known since 1961. It has been used to observe interplanetary plasmas, is implemented in Deep Space Network tracking hardware, and has recently been applied to single-frequency Global Positioning System user navigation This paper discusses exploration at the Goddard Space Flight Center (GSFC) Flight Dynamics Division (FDD) of DRVID synthesized from simultaneous two-way range and Doppler tracking for low Earth-orbiting missions supported by the Tracking and Data Relay Satellite System (TDRSS) The paper presents comparisons of actual DR and ID residuals and relates those comparisons to predictions of the Bent model. The complications due to the pilot tone influence on relayed Doppler measurements are considered. Further use of DRVID to evaluate ionospheric models is discussed, as is use of DRPID in reducing dependence on ionospheric modeling in orbit determination. Author

KEPLER EQUATION SOLVER

F. Landis Markley *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 47-57 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

Kepler's Equation is solved over the entire range of elliptic motion by a fifth-order refinement of the solution of a cubic equation. This method is not iterative, and requires only four transcendental function evaluations: a square root, a cube root, and two trigonometric functions. The maximum relative error of the algorithm is less than one part in 10(exp 18), exceeding the capability of double-precision computer arithmetic. Roundoff errors in double-precision implementation of the algorithm are addressed, and procedures to avoid them are developed. Author

ACCURATE ORBIT DETERMINATION STRATEGIES FOR THE TRACKING AND DATA RELAY SATELLITES

D. H. Oza (Computer Sciences Corp., Lanham, MD.), D. T. Bolvin (Computer Sciences Corp., Lanham, MD.), J. M. Lorah (Computer Sciences Corp., Lanham, MD.), T. Lee (Computer Sciences Corp., Lanham, MD.), and C. E. Doll *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 59-72 (For primary document see N95-27763 09-13)
(Contract NAS5-31500)
Avail: CASI HC A03/MF A04

The National Aeronautics and Space Administration (NASA) has developed the Tracking and Data Relay Satellite (TDRS) System (TDRSS) for tracking and communications support of low Earth-orbiting satellites. TDRSS has the operational capability of providing 85% coverage for TDRSS-user spacecraft. TDRSS currently consists of five geosynchronous spacecraft and the White Sands Complex (WSC) at White Sands, New Mexico. The Bilateration Ranging Transponder System (BRTS) provides range and Doppler measurements for each TDRS. The ground-based BRTS transponders are tracked as if they were TDRSS-user spacecraft. Since the positions of the BRTS transponders are known, their radiometric tracking measurements can be used to provide a well-determined ephemeris for the TDRS spacecraft. For high-accuracy orbit determination of a TDRSS user, such as the Ocean Topography Experiment (TOPEX)/Poseidon spacecraft, high-accuracy TDRS orbits are required. This paper reports on successive refinements in improved techniques and procedures leading to more accurate TDRS orbit determination strategies using the Goddard Trajectory Determination System (GTDS). These strategies range from the standard operational solution using only the BRTS tracking measurements to a sophisticated iterative process involving several successive simultaneous solutions for multiple TDRSs and a TDRSS-user spacecraft. Results are presented for GTDS-generated TDRS ephemerides produced in simultaneous solutions with the TOPEX/Poseidon spacecraft. Strategies with different user spacecraft, as well as schemes for recovering accurate TDRS orbits following a TDRS maneuver, are also presented. In addition, a comprehensive assessment and evaluation of alternative strategies for TDRS orbit determination, excluding BRTS tracking measurements, are presented.

OPERATIONAL IMPROVEMENTS OF LONG-TERM PREDICTED EPHEMERIDES OF THE TRACKING AND DATA RELAY SATELLITES (TDRSs)

J. L. Kostoff (Computer Sciences Corp., Lanham, MD.), D. T. Ward (Computer Sciences Corp., Lanham, MD.), O. O. Cuevas, and R. M. Beckman *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 73-79 (For primary document see N95-27763 09-13)
(Contract NAS5-31500)
Avail: CASI HC A02/MF A04

Tracking and Data Relay Satellite (TDRS) orbit determination and prediction are supported by the Flight Dynamics Facility (FDF) of the Goddard Space Flight Center (GSFC) Flight Dynamics Division (FDD). TDRS System (TDRSS)-user satellites require predicted TDRS ephemerides that are up to 10 weeks in length. Previously, long-term ephemerides generated by the FDF included predictions from the White Sands Complex (WSC), which plans and executes TDRS maneuvers. TDRSs typically have monthly stationkeeping maneuvers, and predicted postmaneuver state vectors are received from WSC up to a month in advance. This paper presents the results of an analysis performed in the FDF to investigate more accurate and economical long-term ephemerides for the TDRSs. As a result of this analysis, two new methods for generating long-term TDRS ephemeris predictions have been implemented by the FDF. The Center-of-Box (COB) method models a TDRS as fixed at the center of its stationkeeping box. Using this method, long-term ephemeris updates are made semiannually instead of weekly. The impulse method is used to model more maneuvers. The impulse method yields better short-term accuracy than the COB method, especially for larger stationkeeping boxes. The accuracy of the impulse method depends primarily on the accuracy of maneuver date forecasting.

A PC-BASED MAGNETOMETER-ONLY ATTITUDE AND RATE DETERMINATION SYSTEM FOR GYROLESS SPACECRAFT

M. Challa (Computer Sciences Corp., Lanham, MD.), G. Natanson (Computer Sciences Corp., Lanham, MD.), J. Deutschmann, and K. Galal *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 83-96 (For primary document see N95-27763 09-13)
(Contract NAS5-31500)
Avail: CASI HC A03/MF A04

This paper describes a prototype PC-based system that uses measurements from a three-axis magnetometer (TAM) to estimate the state (three-axis attitude and rates) of a spacecraft given no a priori information other than the mass properties. The system uses two algorithms that estimate the spacecraft's state - a deterministic magnetic-field only algorithm and a Kalman filter for gyroless spacecraft. The algorithms are combined by invoking the deterministic algorithm to generate the spacecraft state at epoch using a small batch of data and then using this deterministic epoch solution as the initial condition for the Kalman filter during the production run. System input comprises processed data that includes TAM and reference magnetic field data. Additional information, such as control system data and measurements from line-of-sight sensors, can be input to the system if available. Test results are presented using in-flight data from two three-axis stabilized spacecraft: Solar, Anomalous, and Magnetospheric Particle Explorer (SAMPEX) (gyroless, Sun-pointing) and Earth Radiation Budget Satellite (ERBS) (gyro-based, Earth-pointing). The results show that, using as little as 700 s of data, the system is capable of accuracies of 1.5 deg in attitude and 0.01 deg/s in rates; i.e., within SAMPEX mission requirements. Author

DEVELOPMENT OF A DIRECT MATCH TECHNIQUE FOR STAR IDENTIFICATION ON THE SWAS MISSION

Walter K. Daniel (ITHACO Technical Services, Lanham, MD.), Thomas E. Correll, and Mark O. Anderson *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 97 (For primary document see N95-27763 09-13)

Avail: CASI HC A03/MF A04

A direct match technique for star identification was developed for use with the star tracker on the SWAS (Submillimeter Wave Astronomy Satellite) spacecraft. In this technique, tracker searches are used in a two-step process for an implicit direct match star identification. A simulation of the star acquisition process was created and used in the preparation of guide star selection requirements. Flight software implementing this star acquisition technique has been developed and tested. Derived from text

ATTITUDE DETERMINATION USING AN ADAPTIVE MULTIPLE MODEL FILTERING SCHEME

Quang Lam and Surendra N. Ray *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 113-114 (For primary document see N95-27763 09-13)

Avail: CASI HC A01/MF A04

Attitude determination has been considered as a permanent topic of active research and perhaps remaining as a forever-lasting interest for spacecraft system designers. Its role is to provide a reference for controls such as pointing the directional antennas or solar panels, stabilizing the spacecraft or maneuvering the spacecraft to a new orbit. Least Square Estimation (LSE) technique was utilized to provide attitude determination for the Nimbus 6 and G. Despite its poor performance (estimation accuracy consideration), LSE was considered as an effective and practical approach to meet the urgent need and requirement back in the 70's. One reason for this poor performance associated with the LSE scheme is the lack of dynamic filtering or 'compensation'. In other words, the scheme is based totally on the measurements and no attempts were made to model the dynamic equations of motion of the spacecraft. We propose an adaptive filtering approach which employs a bank of Kalman filters to perform robust attitude estimation. The proposed approach, whose architecture is depicted, is essentially based on the latest proof on the interactive multiple model design framework to handle the unknown of the system noise characteristics or statistics. The concept fundamentally employs a bank of Kalman filter or submodel, instead of using fixed values for the system noise statistics for each submodel (per operating condition) as the traditional multiple model approach does, we use an on-line dynamic system noise identifier to 'identify' the system noise level (statistics) and update the filter noise statistics using 'live' information from the sensor model. The advanced noise identifier, whose architecture is also shown, is implemented using an advanced system identifier. To insure the robust performance for the proposed advanced system identifier, it is also further reinforced by a learning system which is implemented (in the outer loop) using neural networks to identify other unknown quantities such as spacecraft dynamics parameters, gyro biases, dynamic disturbances, or environment variations. Derived from text

OBSERVATIONAL MAGNETOMETER CALIBRATION WITH THE HUBBLE SPACE TELESCOPE'S NEW MAGNETOMETERS

Sidney M. Broude *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 115-126 (For primary document see N95-27763 09-13)

(Contract NAS5-31000)

Avail: CASI HC A03/MF A04

The two magnetometers recently replaced on the Hubble Space Telescope during the STS-61 Servicing Mission are now being used successfully for Coarse Attitude Determination during spacecraft vehicle safemode recovery operation. The magnetometer alignments relative to the spacecraft's vehicle's reference frame and the magnetic coupling of the sensors to the four magnetic torquer bars were determined. Coarse Attitude determination errors are now reduced to an average of 0.6 deg. Magnetometer Sensing System calibration and Coarse Attitude determination testing with the new calibration parameters is a geometrical problem. Telemetered earth magnetic field data was collected at twenty-six different vehicle attitudes. The spacecraft attitudes selected were distributed as widely apart as possible throughout the Geocentric Inertial Coordinate reference frame. It is also desirable to sample the Earth's magnetic field over as many different locations of the spacecraft's passage over the Earth as possible, within the limitation of the +/- 28.5 deg orbital inclination. A full range of magnetic moment outputs from the torquer bars needs to be sampled, +/- 3600 ampmeters squared, as well as data when the torquer bars have zero current. Graphic utilities were also developed to visually aid in optimizing the data collection process. Finally, a brief discussion of a method for collecting data for future calibrations is suggested. Author

AN AUTOMATED METHOD OF TUNING AN ATTITUDE ESTIMATOR

Paul A. C. Mason and D. Joseph Mook *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 127-135 (For primary document see N95-27763 09-13)

Avail: CASI HC A02/MF A04

Attitude determination is a major element of the operation and maintenance of a spacecraft. There are several existing methods of determining the attitude of a spacecraft. One of the most commonly used methods utilizes the Kalman filter to estimate the attitude of the spacecraft. Given an accurate model of a system and adequate observations, a Kalman filter can produce accurate estimates of the attitude. If the system model, filter parameters, or observations are inaccurate, the attitude estimates may be degraded. Therefore, it is advantageous to develop a method of automatically tuning the Kalman filter to produce the accurate estimates. In this paper, a three-axis attitude determination Kalman filter, which uses only magnetometer measurements, is developed and tested using real data. The appropriate filter parameters are found via the Process Noise Covariance Estimator (PNCE). The PNCE provides an optimal criterion for determining the best filter parameters. Author

AN MME-BASED ATTITUDE ESTIMATOR USING VECTOR OBSERVATIONS

John L. Crassidis and F. Landis Markley *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 137-151 (For primary document see N95-27763 09-13)

Avail: CASI HC A03/MF A04

In this paper, an optimal batch estimator and filter based on the Minimum Model Error (MME) approach is developed for three-axis stabilized spacecraft. Three different MME algorithms are developed. The first algorithm estimates the attitude of a spacecraft using rate measurements. The second algorithm estimates the attitude without using rate measurements. The absence of rate data may be a result of intentional design or from unexpected failure of existing gyros. The third algorithm determines input-torque modeling error trajectories. All of the algorithms developed in this paper use attitude sensors (e.g., three-axis magnetometers, sun sensors, star trackers, etc.). Results using these new algorithms indicate that an MME-based approach accurately estimates the attitude, rate, and input torque trajectories of an actual spacecraft. Author

POST KALMAN PROGRESS

David Sonnabend *In* NASA. Goddard Space Flight Center, Flight

Mechanics/Estimation Theory Symposium 1995 May 1995 p 153-164 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

In a paper here last year, an idea was put forward that much greater performance could be obtained from an observer, relative to a Kalman filter if more general performance indices were adopted, and the full power spectra of all the noises were employed. The considerable progress since then is reported here. Included are an extension of the theory to regulators, direct calculation of the theory's fundamental quantities - the noise effect integrals - for several theoretical spectra, and direct derivations of the Riccati equations of LQG (Linear-Quadratic-Gaussian) and Kalman theory yielding new insights. DEVELOPMENT OF A ROBUST STAR IDENTIFICATION TECHNIQUE FOR USE IN ATTITUDE DETERMINATION OF THE ACE SPACECRAFT

Mark Woodard and Dave Rohrbaugh (Computer Sciences Corp., Lanham, MD.) *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 167-172 (For primary document see N95-27763 09-13)
Avail: CASI HC A02/MF A04

The Advanced Composition Explorer (ACE) spacecraft is designed to fly in a spin-stabilized attitude. The spacecraft will carry two attitude sensors - a digital fine Sun sensor and a charge coupled device (CCD) star tracker - to allow ground-based determination of the spacecraft attitude and spin rate. Part of the processing that must be performed on the CCD star tracker data is the star identification. Star data received from the spacecraft must be matched with star information in the SKYMAP catalog to determine exactly which stars the sensor is tracking. This information, along with the Sun vector measured by the Sun sensor, is used to determine the spacecraft attitude. Several existing star identification (star ID) systems were examined to determine whether they could be modified for use on the ACE mission. Star ID systems which exist for three-axis stabilized spacecraft tend to be complex in nature and many require fairly good knowledge of the spacecraft attitude, making their use for ACE excessive. Star ID systems used for spinners carrying traditional slit star sensors would have to be modified to model the CCD star tracker. The ACE star ID algorithm must also be robust, in that it will be able to correctly identify stars even though the attitude is not known to a high degree of accuracy, and must be very efficient to allow real-time star identification. The paper presents the star ID algorithm that was developed for ACE. Results from prototype testing are also presented to demonstrate the efficiency, accuracy, and robustness of the algorithm. OPTIMAL ATTITUDE MANEUVER EXECUTION FOR THE ADVANCED COMPOSITION EXPLORER (ACE) MISSION

Mark A. Woodard and David Baker *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 173-183 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

The Advanced Composition Explorer (ACE) spacecraft will require frequent attitude reorientations in order to maintain the spacecraft high gain antenna (HGA) within 3 deg of earth-pointing. These attitude maneuvers will be accomplished by employing a series of ground-commanded thruster pulses, computed by ground operations personnel, to achieve the desired change in the spacecraft angular momentum vector. With each maneuver, attitude nutation will be excited. Large nutation angles are undesirable from a science standpoint. It is important that the thruster firings be phased properly in order to minimize the nutation angle at the end of the maneuver so that science collection time is maximized. The analysis presented derives a simple approximation for the nutation contribution resulting from a series of short thruster burns. Analytic equations are derived which give the induced nutation angle as a function of the number of small thruster burns used to execute the attitude maneuver and the phasing of the burns. The results show that by properly subdividing the attitude burns, the induced nutation can be kept low. The analytic equations are also verified through attitude dynamics simulation and simulation results are presented. Finally, techniques for quantifying the post-maneuver nutation are discussed. EXPERIENCE FROM THE IN-FLIGHT CALIBRATION OF THE EXTREME ULTRAVIOLET EXPLORER (EUVE) AND UPPER ATMOSPHERE RESEARCH SATELLITE (UARS) FIXED HEAD STAR TRACKERS (FHSTs)

Michael Lee *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 185-199 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

Since the original post-launch calibration of the FHSTs (Fixed Head Star Trackers) on EUVE (Extreme Ultraviolet Explorer) and UARS (Upper Atmosphere Research Satellite), the Flight Dynamics task has continued to analyze the FHST performance. The algorithm used for inflight alignment of spacecraft sensors is described and the equations for the errors in the relative alignment for the simple 2 star tracker case are shown. Simulated data and real data are used to compute the covariance of the relative alignment errors. Several methods for correcting the alignment are compared and results analyzed. The specific problems seen on orbit with UARS and EUVE are then discussed. UARS has experienced anomalous tracker performance on an FHST resulting in continuous variation in apparent tracker alignment. On EUVE, the FHST residuals from the attitude determination algorithm showed a dependence on the direction of roll during survey mode. This dependence is traced back to time tagging errors and the original post launch alignment is found to be in error due to the impact of the time tagging errors on the alignment algorithm. The methods used by the FDF (Flight Dynamics Facility) to correct for these problems is described. Author

SAMPEX SPECIAL POINTING MODE

F. Landis Markley, Thomas W. Flatley, and Theodore Leoutsakos (Allied-Signal Technical Services Corp., Lanham, MD.) *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 201-215 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

A new pointing mode has been developed for the Solar, Anomalous, and Magnetospheric Particle Explorer (SAMPEX) spacecraft. This pointing mode orients the instrument boresights perpendicular to the field lines of the Earth's magnetic field in regions of low field strength and parallel to the field lines in regions of high field strength, to allow better characterization of heavy ions trapped by the field. The new mode uses magnetometer signals and is algorithmically simpler than the previous control mode, but it requires increased momentum wheel activity. It was conceived, designed, tested, coded, uplinked to the spacecraft, and activated in less than seven months. Author

USE OF NONLINEAR IDENTIFICATION IN ROBUST ATTITUDE AND ATTITUDE RATE ESTIMATION FOR SAMPEX Abstract Only

D. Joseph Mook, Juan DePena, Kelly Trost, Jung Wen, and Michael McPartland *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 217 (For primary document see N95-27763 09-13)
Avail: CASI HC A01/MF A04

A method is described for obtaining optimal attitude estimation/identification algorithms for spacecraft lacking attitude rate measurement devices (rate gyros), and then demonstrated using actual flight data from the Solar, Anomalous, and Magnetospheric Particle Explorer (SAMPEX) spacecraft. SAMPEX does not have on-board rate sensing, and relies on sun sensors and a three-axis magnetometer for attitude determination. The absence of rate data normally reduces both the total amount of data available and the sampling density (in time) by a substantial fraction. In addition, attitude data is occasionally unavailable (for example, during sun occultation). As a result, the sensitivity of the estimates to model uncertainty and to measurement noise increases. In order to maintain accuracy in the attitude estimates, there is an increased need for accurate models of the rotational dynamics. The Minimum Model Error(MME)/Least Square Correlation(LSC) algorithm accurately identifies an improved model for SAMPEX to be used during periods of complete data loss or extreme noise. The model correction is determined by estimating only one orbit(the identification pass) just prior to the assumed data loss(the prediction pass). The MME estimator correctly predicted the states during the identification phase, but more importantly determines the necessary model correction trajectory, d(t). The LSC algorithm is then used to find this trajectory's functional form, H(x(t)). The results show significant improvement of the new corrected model's attitude estimates as compared to the original uncorrected model's estimates. The possible functional form of the correction term is limited at this point in the study to functions strictly of the estimated states. The results, however, strongly suggest that functions based on the relative position of the satellite may also be possible candidates for future consideration. Author

A SIMPLE METHOD FOR VERIFYING THE DEPLOYMENT OF THE TOMS-EP SOLAR ARRAYS c19

James R. Koppersmith and Eleanor Ketchum *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 219-227
(For primary document see N95-27763 09-13)
Avail: CASI HC A02/MF A04

The Total Ozone Mapping Spectrometer-Earth Probe (TOMS-EP) mission relies upon a successful deployment of the spacecraft's solar arrays. Several methods of verification are being employed to ascertain the solar array deployment status, with each requiring differing amounts of data. This paper describes a robust attitude-independent verification method that utilizes telemetry from the coarse Sun sensors (CSS's) and the three-axis magnetometers (TAM's) to determine the solar array deployment status - and it can do so with only a few, not necessarily contiguous, points of data. The method developed assumes that the solar arrays are deployed. Telemetry data from the CSS and TAM are converted to the Sun and magnetic field vectors in spacecraft body coordinates, and the angle between them is calculated. Deployment is indicated if this angle is within a certain error tolerance of the angle between the reference Sun and magnetic field vectors. Although several other methods can indicate a non-deployed state, with this method there is a 70% confidence level in confirming deployment as well as a nearly 100% certainty in confirming a non-deployed state. In addition, the spacecraft attitude (which is not known during the first orbit after launch) is not needed for this algorithm because the angle between the Sun and magnetic field vectors is independent of the spacecraft attitude. This technique can be applied to any spacecraft with a TAM and with CSS's mounted on the solar array(s). Author

Data from Earth sensor assemblies (ESA's) often are used in the attitude determination (AD) for both spinning and Earth-pointing spacecraft. The ESA's on previous such spacecraft for which the ground-based AD operation was performed by the Flight Dynamics Division (FDD) used the Earth scanning method. AD on such spacecraft requires a model of the shape of the Earth disk as seen from the spacecraft. AD accuracy requirements often are too severe to permit Earth oblateness to be ignored when modeling disk shape. Section 2 of this paper reexamines and extends the methods for Earth disk shape modeling employed in AD work at FDD for the past decade. A new formulation, based on a more convenient Earth flatness parameter, is introduced, and the geometric concepts are examined in detail. It is shown that the Earth disk can be approximated as an ellipse in AD computations. Algorithms for introducing Earth oblateness into the AD process for spacecraft carrying scanning ESA's have been developed at FDD and implemented into the support systems. The Tropical Rainfall Measurement Mission (TRMM) will be the first spacecraft with AD operation performed at FDD that uses a different type of ESA - namely, a static one - containing four fixed detectors D(sub i) (i = 1 to 4). Section 3 of this paper considers the effect of Earth oblateness on AD accuracy for TRMM. This effect ideally will not induce AD errors on TRMM when data from all four D(sub i) are present. When data from only two or three D(sub i) are available, however, a spherical Earth approximation can introduce errors of 0.05 to 0.30 deg on TRMM. These oblateness-induced errors are eliminated by a new algorithm that uses the results of Section 2 to model the Earth disk as an ellipse. Author

A MODIFIED PROPORTIONAL NAVIGATION SCHEME FOR RENDEZVOUS AND DOCKING WITH TUMBLING TARGETS: THE PLANAR CASE c17

Norman Fitz-Coy and Ming-Cheng Liu *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 243-252 (For primary document see N95-27763 09-13)
(Grant NAG8-280)
Avail: CASI HC A02/MF A04

A two-phase proportional navigation scheme is developed for the case of two rigid bodies engaged in a rendezvous/docking maneuver. The target vehicle is nonmaneuvering, but does have constant nonzero angular and linear velocities. Under these conditions, it is shown that previously obtained solutions are not applicable. Analytical solutions are obtained leading to relationships between the transverse and LOS navigation constants. It is shown that the transverse navigation constant for the second phase of the maneuver must be 2. Also, initial conditions necessary for rendezvous are presented. Author

Avail: CASI HC A03/MF A04

The communications antenna on a spin stabilized spacecraft is seldom located on the spin axis, hence, the antenna is in motion relative to the center of mass of the spacecraft. The Doppler shift observed at the ground or space relay communications receivers will include oscillations whose frequency and amplitude are functions of the motion of the antenna and the attitude of the spacecraft relative to the line of sight (LOS). This functional dependence creates the possibility of estimating attitude parameters from Doppler measurements. This paper presents mathematical models of Doppler oscillations from spinning spacecraft, including the effects of nutation. Algorithms for estimating spin rate, attitude and nutation angle are described. Results of analysis of Doppler tracking of GOES-8 and WIND are also discussed. Author

Future plans for planetary exploration currently include using multiple spacecraft to simultaneously explore one planet. This never before encountered situation places new demands on tracking systems used to support navigation. One possible solution to the problem of heavy ground resource conflicts is the use of multispacecraft coherent radio metric data, also known as, bent-pipe data. Analysis of the information content of these data types show that the information content of multi-spacecraft Doppler is dependent only on the frequency of the final downlink leg and is independent of the frequencies used on other legs. Numerical analysis shows that coherent bent-pipe data can provide significantly better capability to estimate the location of a lander on the surface of Mars than can direct lander to Earth radio metric data. However, this is complicated by difficulties in separating the effect of a lander position error from that of an orbiter position error for single passes of data. Author

ULYSSES ORBIT DETERMINATION AT HIGH DECLINATIONS

Timothy P. McElrath and George D. Lewis *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 277-287 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

The trajectory of the Ulysses spacecraft caused its geocentric declination to exceed 60 deg South for over two months during the Fall of 1994, permitting continuous tracking from a single site. During this time, spacecraft operations constraints allowed only Doppler tracking data to be collected, and imposed a high radial acceleration uncertainty on the orbit determination process. The unusual aspects of this situation have motivated a re-examination of the Hamilton-Melbourne results, which have been used before to estimate the information content of Doppler tracking for trajectories closer to the ecliptic. The addition of an acceleration term to this equation is found to significantly increase the declination uncertainty for symmetric passes. In addition, a simple means is described to transform the symmetric results when the tracking pass is non-symmetric. The analytical results are then compared against numerical studies of this tracking geometry and found to be in good agreement for the angular uncertainties. The results of this analysis are applicable to the Near Earth Asteroid Rendezvous (NEAR) mission and to any other missions with high declination trajectories, as well as to missions using short tracking passes and/or one-way Doppler data. APPLICATION OF NON-COHERENT DOPPLER DATA TYPES FOR DEEP SPACE NAVIGATION **c17**

Shyam Bhaskaran *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 289-299 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

Recent improvements in computational capability and Deep Space Network technology have renewed interest in examining the possibility of using one-way Doppler data alone to navigate interplanetary spacecraft. The one-way data can be formulated as the standard differenced-count Doppler or as phase measurements, and the data can be received at a single station or differenced if obtained simultaneously at two stations. A covariance analysis is performed which analyzes the accuracy obtainable by combinations of one-way Doppler data and compared with similar results using standard two-way Doppler and range. The sample interplanetary trajectory used was that of the Mars Pathfinder mission to Mars. It is shown that differenced one-way data is capable of determining the angular position of the spacecraft to fairly high accuracy, but has relatively poor sensitivity to the range. When combined with single station data, the position dispersions are roughly an order of magnitude larger in range and comparable in angular position as compared to dispersions obtained with standard data two-way types. It was also found that the phase formulation is less sensitive to data weight variations and data coverage than the differenced-count Doppler formulation. Author

Future Flight Dynamics systems should take advantage of the possibilities provided by current and future generations of low-cost, high performance workstation computing environments with Graphical User Interface. The port of the existing mainframe Flight Dynamics systems to the workstation environment offers an economic approach for combining the tremendous engineering heritage that has been encapsulated in these systems with the advantages of the new computing environments. This paper will describe the successful transition of the Draper Laboratory R&D version of GTDS (Goddard Trajectory Determination System) from the IBM Mainframe to the Unix workstation environment. The approach will be a mix of historical timeline notes, descriptions of the technical problems overcome, and descriptions of associated SQA (software quality assurance) issues. Author (revised)

As with all NASA facilities, the announcement of reduced budgets, reduced staffing, and the desire to implement smaller/quicker/cheaper missions has required the Agency's organizations to become more efficient in what they do. To accomplish these objectives, the FDD has initiated the development of the Flight Dynamics Distributed System (FDDS). The underlying philosophy of FDDS is to build an integrated system that breaks down the traditional barriers of attitude, mission planning, and navigation support software to provide a uniform approach to flight dynamics applications. Through the application of open systems concepts and state-of-the-art technologies, including object-oriented specification concepts, object-oriented software, and common user interface, communications, data management, and executive services, the FDD will reengineer most of its six million lines of code. DETERMINING GPS AVERAGE PERFORMANCE METRICS Abstract Only **c04**

G. V. Moore *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 307 (For primary document see N95-27763 09-13)
Avail: CASI HC A01/MF A04

Analytic and semi-analytic methods are used to show that users of the GPS constellation can expect performance variations based on their location. Specifically, performance is shown to be a function of both altitude and latitude. These results stem from the fact that the GPS constellation is itself non-uniform. For example, GPS satellites are over four times as likely to be directly over Tierra del Fuego than over Hawaii or Singapore. Inevitable performance variations due to user location occur for ground, sea, air and space GPS users. These performance variations can be studied in an average relative sense. A semi-analytic tool which symmetrically allocates GPS satellite latitude belt dwell times among longitude points is used to compute average performance metrics. These metrics include average number of GPS vehicles visible, relative average accuracies in the radial, intrack and crosstrack (or radial, north/south, east/west) directions, and relative average PDOP or GDOP. The tool can be quickly changed to incorporate various user antenna obscuration models and various GPS constellation designs. Among other applications, tool results can be used in studies to: predict locations and geometries of best/worst case performance, design GPS constellations, determine optimal user antenna location and understand performance trends among various users. A DEMONSTRATION OF UNIFIED TDRS/GPS TRACKING AND ORBIT DETERMINATION

B. Haines, S. Lichten, J. Srinivasan, and L. Young *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 309-320 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

We describe results from an experiment in which TDRS and GPS satellites were tracked simultaneously from a small (3 station) ground network in the western United States. We refer to this technique as 'GPS-like tracking' (GLT) since the user satellite - in this case TDRS - is essentially treated as a participant in the GPS constellation. In the experiment, the TDRS K(sub space-to-ground link (SGL) was tracked together with GPS L-band signals in enhanced geodetic-quality GPS receivers (TurboRogue). The enhanced receivers simultaneously measured and recorded both the TDRS SGL and the GPS carrier phases with sub-mm precision, enabling subsequent precise TDRS orbit determination with differential GPS techniques. A small number of calibrated ranging points from routine operations at the TDRS ground station (White Sands, NM) were used to supplement the GLT measurements in order to improve determination of the TDRS longitude. Various tests performed on TDRS ephemerides derived from data collected during this demonstration - including comparisons with the operational precise orbit generated by NASA Goddard Space Flight Center - provide evidence that the TDRS orbits have been determined to better than 25 m with the GLT technique. This paper evaluates the use of Global Positioning System (GPS) receivers as a primary source of tracking data for low-Earth orbit satellites. GPS data is an alternative to using range, azimuth, elevation, and range-rate (RAER) data from the Air Force Satellite Control Network antennas, the Space Ground Link System (SGLS). This evaluation is applicable to missions such as Skipper, a joint U.S. and Russian atmosphere research mission, that will rely on a GPS receiver as a primary tracking data source. The Detachment 2, Space and Missile Systems Center's Test Support Complex (TSC) conducted the evaluation based on receiver data from the Space Test Experiment Platform Mission O (STEP-O) and Advanced Photovoltaic and Electronics Experiments (APEX) satellites. The TSC performed orbit reconstruction and prediction on the STEP-0 and APEX vehicles using GPS receiver navigation solution data, SGLS RAER data, and SGLS anglesonly (azimuth and elevation) data. For the STEP-O case, the navigation solution based orbits proved to be more accurate than SGLS RAER based orbits. For the APEX case, navigation solution based orbits proved to be less accurate than SGLS RAER based orbits for orbit prediction, and results for orbit reconstruction were inconclusive due to the lack of a precise truth orbit. After evaluating several different GPS data processing methods, the TSC concluded that using GPS navigation solution data is a viable alternative to using SGLS RAER data. Author

The Flight Dynamics Facility (FDF) at the NASA Goddard Space Flight Center (GSFC) has provided operational spacecraft orbit support for many years, currently generating orbit products for about 20 satellites. To date, operational orbit determination in the FDF has been performed on the ground using data from ground-based or space-based tracking systems. Current development of spaceborne Global Positioning System (GPS) receivers is projected to have a significant effect on the support needed for operational satellite navigation. This paper identifies the functions performed in spacecraft navigation and examines and quantifies how the functions and support levels will be affected as onboard GPS receivers are implemented on spacecraft. Cases are considered spacecraft using or not using NASA ground and space networks resources. Author

THE GLOBAL POSITIONING SYSTEM (GPS) AND ATTITUDE DETERMINATION: APPLICATIONS AND ACTIVITIES IN THE FLIGHT DYNAMICS DIVISION
Eleanor Ketchum and Joe Garrick *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 341-349 (For primary document see N95-27763 09-13)
Avail: CASI HC A02/MF A04

The application of GPS to spacecraft attitude determination is a new and growing field. Although the theoretical literature is extensive, space flight testing is currently sparse and inadequate. As an operations organization, the Flight Dynamics Division (FDD) has the responsibility to investigate this new technology, and determine how best to implement the innovation to provide adequate support for future missions. This paper presents some of the current efforts within FDD with regard to GPS attitude determination. This effort specifically addresses institutional capabilities to accommodate a new type of sensor, critically evaluating the literature for recent advancements, and in examining some available -albeit crude- flight data. Avail: CASI HC A03/MF A04

The Total Ozone Mapping Spectrometer-Earth Probe (TOMS-EP) is a polar-orbiting spacecraft designed to measure total ozone levels in the Earth's atmosphere. The nominal mission orbit is a 955-kilometer circular Sun-synchronous orbit with an ascending node mean local crossing time (MLT) between 11:02 a.m. and 11:25 a.m. These two mean local ascending node times constitute the boundaries of the MLT box for this mission. The MLT boundaries were chosen to maintain the Sun-to-Earth-to-vehicle orbit-normal (SVN) angle within a preselected set of seasonally independent boundaries. Because the SVN angle is seasonally dependent, but the MLT is not, contingency options for correcting the MLT of orbital states that fall outside of the required MLT range become time dependent. This paper focuses on contingency orbit adjustment strategies developed at the Goddard Space Flight Center (GSFC) Flight Dynamics Division (FDD) during the mission planning phase of TOMS-EP. Time-dependent delta-V strategies are presented for correcting mission orbit states lying outside of the MLT range. Typically, passive control of the MLT drift rate can be used to restore the orbit state to the required MLT before a seasonal violation of SVN angle constraints can occur. Passive control of the MLT drift rate is obtained through adjustment of the semimajor axis and/or the inclination. The time between initial arrival on orbit at an 'out-of-the box' MLT state and violation of the SVN angle constraints is always less than or equal to 1 year. The choice of which parameter(s) to adjust is dictated by the duration of this time period, the desired mission lifetime, the delta-V cost, and operational constraints. Author

SUMMARY OF EOS FLIGHT DYNAMICS ANALYSIS
Lauri Kraft Newman and David C. Folta *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 365-366 (For primary document see N95-27763 09-13)
Avail: CASI HC A01/MF A04

From a flight dynamics perspective, the Earth Observing System (EOS) spacecraft present a number of challenges to mission designers. The Flight Dynamics Support Branch of NASA GSFC has examined a number of these challenges, including managing the EOS constellation, disposing of the spacecraft at the end-of-life (EOL), and achieving the appropriate mission orbit given launch vehicle and ascent propulsion constraints. The EOS program consists of a number of spacecraft including EOS-AM, an ascending node spacecraft, EOS-PM, a descending node spacecraft, the EOS Chemistry mission (EOS-CHEM), the EOS Altimetry Laser (EOS-LALT), and the EOS-Altimetry Radar (EOS-RALT). The orbit characteristics of these missions are presented. In order to assure that downlinking data from each spacecraft will be possible without interference between any two spacecraft, a careful examination of the relationships between spacecraft and how to maintain the spacecraft in a configuration which would minimize these communications problems must be made. The FDSB has performed various analyses to determine whether the spacecraft will be in a position to interfere with each other, how the orbit dynamics will change the relative positioning of the spacecraft over their lifetimes, and how maintenance maneuvers could be performed, if needed, to minimize communications problems. Prompted by an activity at NASA HQ to set guidelines for spacecraft regarding their end-of-life dispositions, much analysis has also been performed to determine the spacecraft lifetime of EOS-AM1 under various conditions, and to make suggestions regarding the spacecraft disposal. In performing this analysis, some general trends have been observed in lifetime calculations. The paper will present the EOS-AM1 lifetime results, comment on general reentry conclusions, and discuss how these analyses reflect on the HQ NMI. Placing the EOS spacecraft into their respective mission orbits involves some intricate maneuver planning to assure that all mission orbit requirements are met, given the initial conditions supplied by the launch vehicle at injection. The FDSB has developed an ascent scenario to meet the mission requirements. This paper presents results of the ascent analysis. Author

GEOSTATIONARY OPERATIONAL ENVIRONMENTAL SATELLITE (GOES)-8 MISSION FLIGHT EXPERIENCE c18

C. H. Noonan (Computer Sciences Corp., Lanham, MD.), R. J. McIntosh (Computer Sciences Corp., Lanham, MD.), J. N. Rowe (Computer Sciences Corp., Lanham, MD.), R. L. DeFazio, and K. F. Galal *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 369-378
(For primary document see N95-27763 09-13)
(Contract NAS5-31500)
Avail: CASI HC A02/MF A04

The Geostationary Operational Environmental Satellite (GOES)-8 spacecraft was launched on April 13, 1994, at 06:04:02 coordinated universal time (UTC), with separation from the Atlas-Centaur launch vehicle occurring at 06:33:05 UTC. The launch was followed by a series of complex, intense operations to maneuver the spacecraft into its geosynchronous mission orbit. The Flight Dynamics Facility (FDF) of the Goddard Space Flight Center (GSFC) Flight Dynamics Division (FDD) was responsible for GOES-8 attitude, orbit maneuver, orbit determination, and station acquisition support during the ascent phase. This paper summarizes the efforts of the FDF support teams and highlights some of the unique challenges the launch team faced during critical GOES-8 mission support. FDF operations experience discussed includes: (1) The abort of apogee maneuver firing-1 (AMF-1), cancellation of AMF-3, and the subsequent replans of the maneuver profile; (2) The unexpectedly large temperature dependence of the digital integrating rate assembly (DIRA) and its effect on GOES-8 attitude targeting in support of perigee raising maneuvers; (3) The significant effect of attitude control thrusting on GOES-8 orbit determination solutions; (4) Adjustment of the trim tab to minimize torque due to solar radiation pressure; and (5) Postlaunch analysis performed to estimate the GOES-8 separation attitude. The paper also discusses some key FDF GOES-8 lessons learned to be considered for the GOES-J launch which is currently scheduled for May 19, 1995. Author

This paper presents an extended Kalman filter for estimating attitude sensor timing errors. Spacecraft attitude is determined by finding the mean rotation from a set of reference vectors in inertial space to the corresponding observed vectors in the body frame. Any timing errors in the observations can lead to attitude errors if either the spacecraft is rotating or the reference vectors themselves vary with time. The state vector here consists of the attitude quaternion, timetag biases, and, optionally, gyro drift rate biases. The filter models the timetags as random walk processes: their expectation values propagate as constants and white noise contributes to their covariance. Thus, this filter is applicable to cases where the true timing errors are constant or slowly varying. The observability of the state vector is studied first through an examination of the algebraic observability condition and then through several examples with simulated star tracker timing errors. The examples use both simulated and actual flight data from the Extreme Ultraviolet Explorer (EUVE). The flight data come from times when EUVE had a constant rotation rate, while the simulated data feature large angle attitude maneuvers. The tests include cases with timetag errors on one or two sensors, both constant and time-varying, and with and without gyro bias errors. Due to EUVE's sensor geometry, the observability of the state vector is severely limited when the spacecraft rotation rate is constant. In the absence of attitude maneuvers, the state elements are highly correlated, and the state estimate is unreliable. The estimates are particularly sensitive to filter mistuning in this case. The EUVE geometry, though, is a degenerate case having coplanar sensors and rotation vector. Observability is much improved and the filter performs well when the rate is either varying or noncoplanar with the sensors, as during a slew. Even with bad geometry and constant rates, if gyro biases are independently known, the timetag error for a single sensor can be accurately estimated as long as its boresight is not too close to the spacecraft rotation axis. Author

A NEW ANGLE ON THE EULER ANGLES c64

F. Landis Markley and Malcolm D. Shuster (Florida Univ., Gainesville, FL.) *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 395-403 (For primary document see N95-27763 09-13)
Avail: CASI HC A02/MF A04

We present a generalization of the Euler angles to axes beyond the twelve conventional sets. The generalized Euler axes must satisfy the constraint that the first and the third are orthogonal to the second; but the angle between the first and third is arbitrary, rather than being restricted to the values 0 and pi/2, as in the conventional sets. This is the broadest generalization of the Euler angles that provides a representation of an arbitrary rotation matrix. The kinematics of the generalized Euler angles and their relation to the attitude matrix are presented. As a side benefit, the equations for the generalized Euler angles are universal in that they incorporate the equations for the twelve conventional sets of Euler angles in a natural way. Author

The Passive Aerodynamically Stabilized Magnetically Damped Satellite (PAMS) will be deployed from the Space Shuttle and used as a target for a Shuttle-mounted laser. It will be a cylindrical satellite with several corner cube reflectors on the ends. The center of mass of the cylinder will be near one end, and aerodynamic torques will tend to align the axis of the cylinder with the spacecraft velocity vector. Magnetic hysteresis rods will be used to provide passive despin and oscillation-damping torques on the cylinder. The behavior of the hysteresis rods depends critically on the 'B/H' curves for the combination of materials and rod length-to-diameter ratio ('l-over-d'). These curves are qualitatively described in most Physics textbooks in terms of major and minor 'hysteresis loops'. Mathematical modeling of the functional relationship between B and H is very difficult. In this paper, the physics involved is not addressed, but an algorithm is developed which provides a close approximation to empirically determined data with a few simple equations suitable for use in computer simulations. AUTONOMOUS CONTROL SYSTEM RECONFIGURATION FOR SPACECRAFT WITH NON-REDUNDANT ACTUATORS Abstract Only c18

Walter Grossman *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 417 (For primary document see N95-27763 09-13)
Avail: CASI HC A01/MF A04

The Small Satellite Technology Initiative (SSTI) 'CLARK' spacecraft is required to be single-failure tolerant, i.e., no failure of any single component or subsystem shall result in complete mission loss. Fault tolerance is usually achieved by implementing redundant subsystems. Fault tolerant systems are therefore heavier and cost more to build and launch than non-redundent, non fault-tolerant spacecraft. The SSTI CLARK satellite Attitude Determination and Control System (ADACS) achieves single-fault tolerance without redundancy. The attitude determination system system uses a Kalman Filter which is inherently robust to loss of any single attitude sensor. The attitude control system uses three orthogonal reaction wheels for attitude control and three magnetic dipoles for momentum control. The nominal six-actuator control system functions by projecting the attitude correction torque onto the reaction wheels while a slower momentum management outer loop removes the excess momentum in the direction normal to the local B field. The actuators are not redundant so the nominal control law cannot be implemented in the event of a loss of a single actuator (dipole or reaction wheel). The spacecraft dynamical state (attitude, angular rate, and momentum) is controllable from any five-element subset of the six actuators. With loss of an actuator the instantaneous control authority may not span R(3) but the controllability gramian integral(limits between t,0) Phi(t, tau)B(tau)B(prime)(tau) Phi(prime)(t, tau)d tau retains full rank. Upon detection of an actuator failure the control torque is decomposed onto the remaining active axes. The attitude control torque is effected and the over-orbit momentum is controlled. The resulting control system performance approaches that of the nominal system. Author

CONTINGENCY DESIGNS FOR ATTITUDE DETERMINATION OF TRMM

John L. Crassidis, Stephen F. Andrews, F. Landis Markley, and Kong Ha (Orbital Sciences Corp., Greenbelt, MD.) *In its* Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 419-433 Sponsored by National Research Council Postdoctoral Fellowship (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

In this paper, several attitude estimation designs are developed for the Tropical Rainfall Measurement Mission (TRMM) spacecraft. A contingency attitude determination mode is required in the event of a primary sensor failure. The final design utilizes a full sixth-order Kalman filter. However, due to initial software concerns, the need to investigate simpler designs was required. The algorithms presented in this paper can be utilized in place of a full Kalman filter, and require less computational burden. These algorithms are based on filtered deterministic approaches and simplified Kalman filter approaches. Comparative performances of all designs are shown by simulating the TRMM spacecraft in mission mode. Comparisons of the simulation results indicate that comparable accuracy with respect to a full Kalman filter design is possible. Author

ORION: A SUPERSYNCHRONOUS TRANSFER ORBIT MISSION

I. M. Walters, J. F. Baker, and I. M. Shurmer *In* NASA. Goddard Space Flight Center, Flight Mechanics/Estimation Theory Symposium 1995 May 1995 p 435-447 (For primary document see N95-27763 09-13)
Avail: CASI HC A03/MF A04

ORION F1 was launched on 29th November 1994 on an Atlas IIA launch vehicle. It was designed, built and delivered in-orbit by Matra Marconi Space Systems Plc and was handed over to ORION Satellite Corporation on 20th January 1995 at its on-station longitude of 37.5 deg W. The mission differed significantly from that of any other geostationary communications satellite in that the Transfer Orbit apogee altitude of 123,507 km was over three times geosynchronous (GEO) altitude and one third of the way to the moon. The SuperSynchronous Transfer Orbit (SSTO) mission is significantly different from the standard Geostationary Transfer Orbit (GTO)mission in a number of ways. This paper discusses the essential features of the mission design through its evolution since 1987 and the details of the highly successful mission itself including a detailed account of the attitude determination achieved using the Galileo Earth and Sun Sensor (ESS). A HIGH VELOCITY ELECTROMAGNETIC MASS LAUNCHER HAVING AN ABLATION RESISTANT INSULATOR Patent Application

Robert A. Meger, inventor (to Navy) 1 Jun. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288231; US-Patent-Appl-SN-252474) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A railgun having a composite insulator of laminated materials positioned between the rails is described in this document. The composite insulator is comprised of a series of conducting layers oriented with the edges toward the bore, or barrel, of the railgun and the wide edges away from the bore. The laminate is lain lengthwise along the rails and comprised of conducting layers of a high heat conductivity metal interleaved with an insulator material. The insulator material allows the composite insulator to stand off the voltages in a plasma armature even under high radiation flux conditions. Below the conducting material's ablation threshold the amount of ablation produced by the composite insulator is reduced by the reduction of insulator surface area exposed to the radiation. This allows better control of armature growth, mass acceleration by the plasma armature, secondary formation, and other factors normally found to retard projectile acceleration. DTIC

REUSABLE LAUNCH VEHICLE DEVELOPMENT RESEARCH Final Report

16 Jan. 1995 47 p
(Contract NAS8-40257)
(NASA-CR-196614; NAS 1.26:196614) Avail: CASI HC A03/MF A01

NASA has generated a program approach for a SSTO reusable launch vehicle technology (RLV) development which includes a follow-on to the Ballistic Missile Defense Organization's (BMDO) successful DC-X program, the DC-XA (Advanced). Also, a separate sub-scale flight demonstrator, designated the X-33, will be built and flight tested along with numerous ground based technologies programs. For this to be a successful effort, a balance between technical, schedule, and budgetary risks must be attained. The adoption of BMDO's 'fast track' management practices will be a key element in the eventual success of NASA's effort. Derived from text

SOME MECHANICAL DESIGN ASPECTS OF THE EUROPEAN ROBOTIC ARM **c37**

Peter J. Lambooy, Wart M. Mandersloot, and Richard H. Bentall (European Space Agency. European Space Research and Technology Center, ESTEC, Noordwijk, Netherlands.) *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 17-29 (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

The European Robotic Arm (ERA) is a contribution to the Russian Segment of the International Space Station Alpha. It will start operating on the Russian Segment during the assembly phase. ERA is designed and produced by a large industrial consortium spread over Europe with Fokker Space & Systems as prime contractor. In this paper, we will describe some of the overall design aspects and focus on the development of several mechanisms within ERA. The operation of ERA during the approach of its end effector towards the grapple interface and the grapple operation is discussed, with a focus on mechanisms. This includes the geometry of the end effector leading edge, which is carefully designed to provide the correct and complete tactile information to a torque-force sensor (TFS). The data from this TFS are used to steer the arm such that forces and moments are kept below 20 N and 20 N.m respectively during the grappling operation. Two hardware models of the end effector are built. The problems encountered are described as well as their solutions. The joints in the wrists and the elbow initially used a harmonic drive lubricated by MoS2. During development testing, this combination showed an insufficient lifetime in air to survive the acceptance test program. The switch-over to a system comprising planetary gearboxes with grease lubrication is described. From these development efforts, conclusions are drawn and recommendations are given for the design of complex space mechanisms. Author

An innovative new telerobotic inspection system called STAR (the Satellite Test Assistant Robot) has been developed to assist engineers as they test new spacecraft designs in simulated space environments. STAR operates inside the ultra-cold, high-vacuum, test chambers and provides engineers seated at a remote Operator Control Station (OCS) with high resolution video and infrared (IR) images of the flight articles under test. STAR was successfully proof tested in JPL's 25-ft (7.6-m) Space Simulation Chamber where temperatures ranged from +85 C to -190 C and vacuum levels reached 5.1 x 10(exp -6) torr. STAR's IR Camera was used to thermally map the entire interior of the chamber for the first time. STAR also made several unexpected and important discoveries about the thermal processes occurring within the chamber. Using a calibrated test fixture arrayed with ten sample spacecraft materials, the IR camera was shown to produce highly accurate surface temperature data. This paper outlines STAR's design and reports on significant results from the thermal vacuum chamber test. Author

THE ALPHA-PROTON-X-RAY SPECTROMETER DEPLOYMENT MECHANISM: AN ANTHROPOMORPHIC APPROACH TO SENSOR PLACEMENT ON MARTIAN ROCKS AND SOIL **c91**

Richard S. Blomquist *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 61-78 (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

On July 4,1997, the Mars Pathfinder spacecraft lands on Mars and starts conducting technological and scientific experiments. One experiment, the Alpha-Proton-X-ray Spectrometer, uses a sensor head placed against rocks and soil to determine their composition. To guarantee proper placement, a deployment mechanism mounted on the Mars Rover aligns the sensor head to within 20 deg of the rock and soil surfaces. In carrying out its task, the mechanism mimics the action of a human hand and arm. Consisting of a flexible wrist, a parallel link arm, a brush dc motor actuator, and a revolutionary non-pyrotechnic fail-safe release device, the mechanism correctly positions the sensor head on rocks as high as 0.29 m and on targets whose surfaces are tilted as much as 45 deg from the nominal orientation of the sensor head face. The mechanism weighs less than 0.5 kg, can withstand 100 g's, and requires less than 2.8 N x m of actuation torque. The fail-safe coupler utilizes Cerrobend, a metal alloy that melts at 60 C, to fuse the actuator and the rest of the mechanism together. A film heater wrapped around the coupler melts the metal, and Negator springs drive the mechanism into its stowed position. The fail-safe actuates using 6.75 Watts for 5 minutes in the event of an actuator failure. Author

Avail: CASI HC A03/MF A04

The Clementine spacecraft was developed under the 'faster, better, cheaper' theme. The constraints of a low budget coupled with an unusually tight schedule forced many departures from the normal spacecraft development methods. This paper discusses technical lessons learned about several of the mechanisms on the Clementine spacecraft as well as managerial lessons learned for the entire mechanisms subsystem. A quick overview of the Clementine mission is included; the mission schedule and environment during the mechanisms releases and deployment are highlighted. This paper then describes the entire mechanisms subsystem. The design and test approach and key philosophies for a fast-track program are discussed during the description of the mechanisms subsystem. The mechanism subsystem included a marman clamp separation system, a separation nut separation system, a solar panel deployment and pointing system, a high gain antenna feed deployment system, and two separate sensor cover systems. Each mechanism is briefly discussed. Additional technical discussion is given on the marman clamp design, the sensor cover designs, and the design and testing practices for systems driven by heated actuators (specifically paraffin actuators and frangibolts). All of the other mechanisms were of conventional designs and will receive less emphasis. Lessons learned are discussed throughout the paper as they applied to the systems being discussed. Since there is information on many different systems, this paper is organized so that information on a particular topic can be quickly referenced. Author

LOW-COST TUBULAR ANTENNA DEPLOYER FOR WISP-2 **c37**
Robert M. Warden *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 131-135 (For primary document see N95-27260 09-15)
Avail: CASI HC A01/MF A04

A new tubular boom deployment mechanism has been designed, built, and flown as part of the second Waves In Space Program (WISP-2) through Cornell University. For this program, two booms were needed to form a dipole antenna but existing units were found to be too complicated and costly. A low-cost alternative was developed which combined flight-proven tubular boom technology with a new support and deployment mechanism. The simplicity of this new design was a major factor in providing a highly reliable and cost-effective system. Author

HIGH PERFORMANCE STEPPER MOTORS FOR SPACE MECHANISMS **c33**
Patrick Sega and Christine Estevenon *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 141-146 Sponsored by CNES (For primary document see N95-27260 09-15)
Avail: CASI HC A02/MF A04

Hybrid stepper motors are very well adapted to high performance space mechanisms. They are very simple to operate and are often used for accurate positioning and for smooth rotations. In order to fulfill these requirements, the motor torque, its harmonic content, and the magnetic parasitic torque have to be properly designed. Only finite element computations can provide enough accuracy to determine the toothed structures' magnetic permeance, whose derivative function leads to the torque. It is then possible to design motors with a maximum torque capability or with the most reduced torque harmonic content (less than 3 percent of fundamental). These later motors are dedicated to applications where a microstep or a synchronous mode is selected for minimal dynamic disturbances. In every case, the capability to convert electrical power into torque is much higher than on DC brushless motors. Author

DEVELOPMENT OF A MINIATURE ACTUATOR/CONTROLLER SYSTEM **c33**
Scott P. Stanley *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 147-151 (For primary document see N95-27260 09-15)
Avail: CASI HC A01/MF A04

Development of new products is often hampered or prevented by the cost and resource commitments required by a traditional engineering approach. Schaeffer Magnetics, Inc. identified the potential need for a miniature incremental actuator with an integrated controller but did not want the development to be subject to the obstacles inherent in the traditional approach. In response a new approach - the Pathfinder Engineering Program (PEP) - was developed to streamline new product generation and improve product quality. The actuator/controller system resulting from implementation of this new procedure is an exceptionally compact and self-contained device with many applications. Author

BASIC SPACE PAYLOAD FASTENER **c37**
J. M. Vranish and Stephen Gorevan (Honeybee Robotics Ltd., New York, NY.) *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 152-157 (For primary document see N95-27260 09-15)
Avail: CASI HC A02/MF A04

A new basic space fastener has been developed and tested by the GSFC. The purposes of this fastener are to permit assembly and servicing in space by astronauts and/or robots and to facilitate qualification of payloads on Earth prior to launch by saving time and money during the systems integration and component testing and qualification processes. The space fastener is a rework of the basic machine screw such that crossthreading is impossible; it is self-locking and will not work its way out during launch (vibration proof); it will not wear out despite repeated use; it occupies a small foot print which is comparable to its machine screw equivalent, and it provides force and exhibits strength comparable to its machine screw equivalent. Construction is ultra-simple and cost effective and the principle is applicable across the full range of screw sizes ranging from a #10 screw to 2.5 cm (1 in) or more. In this paper, the fastener principles of operation will be discussed along with test results and construction details. The new fastener also has considerable potential in the commercial sector. A few promising applications will be presented. Author

This paper describes the preliminary development of a high force thermal latch (HFTL). The HFTL has one moving part which is restrained in the latched position by a low melting temperature or fusible metal alloy. When heated the fusible alloy flows to a receiving chamber and in so doing at first releases the tension load in the latch bolt and later releases the bolt itself. The HFTL can be used in place of pyrotechnically activated spacecraft release devices in those instances where the elimination of both pyrotechnic shock-loading and rapid strain-energy release take precedence over the near instantaneous release offered by ordnance initiated devices. NASA's Mars Pathfinder mission, to be launched in 1996, reflects a new philosophy of exploiting new technologies to reduce mission cost and accelerate the pace of space exploration. One of the experiments on board Pathfinder will demonstrate the first use in space of a multi-cycle, electrically-activated, shape-memory alloy (SMA) actuator. SMA's are metal alloys which, when heated, undergo a crystalline phase change. This change in phase alters the alloy lattice-constant, resulting in a change of dimension. Upon cooling, the alloy returns to its original lattice formation. Wire drawn from an SMA contracts in length when heated. The reversible change in length is 3 percent to 5 percent. The wire used in this actuator is a nickel-titanium alloy known as nitinol. Author

This paper describes a system added to an existing satellite-borne telescope design for the purpose of compensating the boresight errors that had been observed in earlier flights of similar instruments. Those errors had been found to be caused by thermal distortion of the spaceframe. This retrofit design was subjected to severe volume restrictions because it was fitted into an already tightly-packaged instrument envelope. It was found practical to improve the basic design by converting a redundant structure into a statically-determinate one. It was also possible to use portions of the mechanical actuation system to facilitate the position encoding needed for computer interfacing. Author

SPECIAL FEATURES OF THE CLUSTER ANTENNA AND RADIAL BOOMS DESIGN, DEVELOPMENT AND VERIFICATION c18
G. Gianfiglio, M. Yorck, and H. J. Luhmann *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 221-237 (For primary document see N95-27260 09-15)
Avail: CASI HC A03/MF A04

CLUSTER is a scientific space mission to in-situ investigate the Earth's plasma environment by means of four identical spin-stabilized spacecraft. Each spacecraft is provided with a set of four rigid booms: two Antenna Booms and two Radial Booms. This paper presents a summary of the boom development and verification phases addressing the key aspects of the Radial Boom design. In particular, it concentrates on the difficulties encountered in fulfilling simultaneously the requirements of minimum torque ratio and maximum allowed shock loads at boom latching for this two degree of freedom boom. The paper also provides an overview of the analysis campaign and testing program performed to achieve sufficient confidence in the boom performance and operation. Author

FORTE ANTENNA ELEMENT AND RELEASE MECHANISM DESIGN c37
David J. Rohweller and Thomas A. Butler (Los Alamos National Lab., NM.) *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 238-252 (For primary document see N95-27260 09-15)
Avail: CASI HC A03/MF A04

The Fast On-Orbit Recording of Transient Events (FORTE) satellite being built by Los Alamos National Laboratory (LANL) and Sandia National Laboratories (SNL) has as its most prominent feature a large deployable (11 m by 5 m) log periodic antenna to monitor emissions from electrical storms on the Earth. This paper describes the antenna and the design for the long elements and explains the dynamics of their deployment and the damping system employed. It also describes the unique paraffin-actuated reusable tie-down and release mechanism employed in the system. Author

DEPLOYMENT AND RETRACTION OF A CABLE-DRIVEN SOLAR ARRAY: TESTING AND SIMULATION c37

P. Kumar and S. Pellegrino *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 253-267 Sponsored by Cambridge Commonwealth Trust (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

The paper investigates three critical areas in cable-driven rigid-panel solar arrays: First, the variation of deployment and retraction cable tensions due to friction at the hinges; Second, the change in deployment dynamics associated with different deployment histories; Third, the relationship between the level of pre-tension in the closed contact loops and the synchronization of deployment. A small scale model array has been made and tested, and its behavior has been compared to numerical simulations. Author

EFFECTS OF BEARING CLEANING AND LUBE ENVIRONMENT ON BEARING PERFORMANCE c37

Peter C. Ward *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 285-300 Sponsored by Hamilton Standard; and United Technologies (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

Running torque data of SR6 ball bearings are presented for different temperatures and speeds. The data are discussed in contrast to generally used torque prediction models and point out the need to obtain empirical data in critical applications. Also, the effects of changing bearing washing techniques from old, universally used CFC-based systems to CFC-free aqueous/alkaline solutions are discussed. Data on wettability, torque and lubricant life using SR3 ball bearings are presented. In general, performance is improved using the new aqueous washing techniques. Author

BALL BEARING VIBRATIONS AMPLITUDE MODELING AND TEST COMPARISONS c37

Richard A. Hightower, III and Dave Bailey *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 301-315 (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

Bearings generate disturbances that, when combined with structural gains of a momentum wheel, contribute to induced vibration in the wheel. The frequencies generated by a ball bearing are defined by the bearing's geometry and defects. The amplitudes at these frequencies are dependent upon the actual geometry variations from perfection; therefore, a geometrically perfect bearing will produce no amplitudes at the kinematic frequencies that the design generates. Because perfect geometry can only be approached, emitted vibrations do occur. The most significant vibration is at the spin frequency and can be balanced out in the build process. Other frequencies' amplitudes, however, cannot be balanced out. Momentum wheels are usually the single largest source of vibrations in a spacecraft and can contribute to pointing inaccuracies if emitted vibrations ring the structure or are in the high-gain bandwidth of a sensitive pointing control loop. It is therefore important to be able to provide an a priori knowledge of possible amplitudes that are singular in source or are a result of interacting defects that do not reveal themselves in normal frequency prediction equations. This paper will describe the computer model that provides for the incorporation of bearing geometry errors and then develops an estimation of actual amplitudes and frequencies. Test results were correlated with the model. A momentum wheel was producing an unacceptable 74 Hz amplitude. The model was used to simulate geometry errors and proved successful in identifying a cause that was verified when the parts were inspected. Author

A CRYOGENIC SCAN MECHANISM FOR USE IN FOURIER TRANSFORM SPECTROMETERS c35

Claef F. Hakun and Kenneth A. Blumenstock *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 316-333 (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

This paper describes the requirements, design, assembly and testing of the linear Scan Mechanism (SM) of the Composite Infrared Spectrometer (CIRS) Instrument. The mechanism consists of an over constrained flexible structure, an innovative moving magnet actuator, passive eddy current dampers, a Differential Eddy Current (DEC) sensor, Optical Limit Sensors (OLS), and a launch lock. Although all the components of the mechanism are discussed, the flexible structure and the magnetic components are the primary focus. Several problems encountered and solutions implemented during the development of the scan mechanism are also described. Author

HIGH-PERFORMANCE REACTIONLESS SCAN MECHANISM c74

Ellen I. Williams, Richard T. Summers, and Miroslaw A. Ostaszewski *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 334-349 Sponsored by Dick Maxwell (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

A high-performance reactionless scan mirror mechanism was developed for space applications to provide thermal images of the Earth. The design incorporates a unique mechanical means of providing reactionless operation that also minimizes weight, mechanical resonance operation to minimize power, combined use of a single optical encoder to sense coarse and fine angular position, and a new kinematic mount of the mirror. A flex pivot hardware failure and current project status are discussed. Author

LINEAR PROOF MASS ACTUATOR c37

S. E. Holloway, III *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 368-380 (For primary document see N95-27260 09-15)

Avail: CASI HC A03/MF A04

This paper describes the mechanical design, analysis, fabrication, testing, and lessons learned by developing a uniquely designed spaceflight-like actuator. The Linear Proof Mass Actuator (LPMA) was designed to attach to both a large space structure and a ground test model without modification.

Previous designs lacked the power to perform in a terrestrial environment while other designs failed to produce the desired accelerations or frequency range for spaceflight applications. Thus, the design for a unique actuator was conceived and developed at NASA Langley Research Center. The basic design consists of four large mechanical parts (Mass, Upper Housing, Lower Housing, and Center Support) and numerous smaller supporting components including an accelerometer, encoder, and four drive motors. Fabrication personnel were included early in the design phase of the LPMA as part of an integrated manufacturing process to alleviate potential difficulties in machining an already challenging design. Operational testing of the LPMA demonstrated that the actuator is capable of various types of load functions. Author

LOAD MEASUREMENT SYSTEM WITH LOAD CELL LOCK-OUT MECHANISM **c37**

Thang Le, Monty Carroll, and Jonathan Liu *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 381-392 (For primary document see N95-27260 09-15)
Avail: CASI HC A03/MF A04

In the frame work of the project Shuttle Plume Impingement Flight Experiment (SPIFEX), a Load Measurement System was developed and fabricated to measure the impingement force of Shuttle Reaction Control System (RCS) jets. The Load Measurement System is a force sensing system that measures any combination of normal and shear forces up to 40 N (9 lbf) in the normal direction and 22 N (5 lbf) in the shear direction with an accuracy of +/- 0.04 N (+/- 0.01 lbf) Since high resolution is required for the force measurement, the Load Measurement System is built with highly sensitive load cells. To protect these fragile load cells in the non-operational mode from being damaged due to flight loads such as launch and landing loads of the Shuttle vehicle, a motor driven device known as the Load Cell Lock-Out Mechanism was built. This Lock-Out Mechanism isolates the load cells from flight loads and re-engages the load cells for the force measurement experiment once in space. With this highly effective protection system, the SPIFEX load measurement experiment was successfully conducted on STS-44 in September 1994 with all load cells operating properly and reading impingement forces as expected. MICROMECHANISMS FOR OPTIMISM SEISMOMETER **c37**

Nicolas Paulin, Pierre Dumas, and Marc Pochard *In* NASA. Johnson Space Center, The 29th Aerospace Mechanisms Symposium May 1995 p 393-400 (For primary document see N95-27260 09-15)
Avail: CASI HC A02/MF A04

Within the framework of the Mars 94 mission, it was decided to design and build a new vertical axis seismometer in order to continuously record the seismic events occurring on the Mars planet. The mission requirements lead to very stringent constraints on power, volume, mass and shock resistance at the landing. The seismometer must be capable of automatic leveling and automatic fitting to the local gravity. This paper deals with the mechanisms designed for this seismometer. Due to the short allotted time for its development and low cost, the baseline was to apply the rules of spatial tribology and, when it was possible, to customize existing components for space applications. ORBITAL IMPACTS AND THE SPACE SHUTTLE WINDSHIELD

Karen S. Edelstein 1 Mar. 1995 10 p Presented at Aerospace/Defense Sensing and Dual-Use Photonics, Orlando, FL, 17-21 Apr. 1995
(NASA-TM-110594; NAS 1.15:110594) Avail: CASI HC A02/MF A01

The Space Transportation System (STS) fleet has flown more than sixty missions over the fourteen years since its first flight. As a result of encounters with on-orbit particulates (space debris and micrometeoroids), 177 impact features (chips) have been found on the STS outer windows (through STS-65). Forty-five of the damages were large enough to warrant replacement of the window. NASA's orbital operations and vehicle inspection procedures have changes over the history of the shuttle program, in response to concerns about the orbital environment and the cost of maintaining the space shuttle. These programmatic issues will be discussed, including safety concerns, maintenance issues, inspection procedures and flight rule changes. Examples of orbital debris impacts to the shuttle windows will be provided. There will also be a brief discussion of the impact properties of glass and what design changes have been considered to improve the impact properties of the windows. Author

(Contract NASw-4911)
(NASA-CR-197808; NAS 1.26:197808; SAICNY95-02-25-Vol-1) Avail: CASI HC A08/MF A02

This document is the Executive Summary of a technical report on a probabilistic risk assessment (PRA) of the Space Shuttle vehicle performed under the sponsorship of the Office of Space Flight of the US National Aeronautics and Space Administration. It briefly summarizes the methodology and results of the Shuttle PRA. The primary objective of this project was to support management and engineering decision-making with respect to the Shuttle program by producing (1) a quantitative probabilistic risk model of the Space Shuttle during flight, (2) a quantitative assessment of in-flight safety risk, (3) an identification and prioritization of the design and operations that principally contribute to in-flight safety risk, and (4) a mechanism for risk-based evaluation proposed modifications to the Shuttle System. Secondary objectives were to provide a vehicle for introducing and transferring PRA technology to the NASA community, and to demonstrate the value of PRA by applying it beneficially to a real program of great international importance. Derived from text

PROBABILISTIC RISK ASSESSMENT OF THE SPACE SHUTTLE. PHASE 3: A STUDY OF THE POTENTIAL OF LOSING THE VEHICLE DURING NOMINAL OPERATION. VOLUME 2: INTEGRATED LOSS OF VEHICLE MODEL

Joseph R. Fragola, Gaspare Maggio, Michael V. Frank (Safety Factors Associates, Inc., Encinitas, CA.), Luis Gerez (Empresarios Agrupados, Madrid, Spain.), Richard H. McFadden, Erin P. Collins, Jorge Ballesio, Peter L. Appignani, and James J. Karns 28 Feb. 1995 581 p
(Contract NASw-4911)
(NASA-CR-197809; NAS 1.26:197809; SAICNY95-02-25-Vol-2) Avail: CASI HC A25/MF A06

The application of the probabilistic risk assessment methodology to a Space Shuttle environment, particularly to the potential of losing the Shuttle during nominal operation is addressed. The different related concerns are identified and combined to determine overall program risks. A fault tree model is used to allocate system probabilities to the subsystem level. The loss of the vehicle due to failure to contain energetic gas and debris, to maintain proper propulsion and configuration is analyzed, along with the loss due to Orbiter, external tank failure, and landing failure or error. DEVELOPMENT OF NUMERICAL METHODS FOR OVERSET GRIDS WITH APPLICATIONS FOR THE INTEGRATED SPACE SHUTTLE VEHICLE Final Report

William M. Chan Jan. 1995 77 p Original contains color illustrations
(Contract NCC2-654)
(NASA-CR-197759; NAS 1.26:197759) Avail: CASI HC A05/MF A01; 1 functional color page

Algorithms and computer code developments were performed for the overset grid approach to solving computational fluid dynamics problems. The techniques developed are applicable to compressible Navier-Stokes flow for any general complex configurations. The computer codes developed were tested on different complex configurations with the Space Shuttle launch vehicle configuration as the primary test bed. General, efficient and user-friendly codes were produced for grid generation, flow solution and force and moment computation. Author

DEBRIS/ICE/TPS ASSESSMENT AND INTEGRATED PHOTOGRAPHIC ANALYSIS OF SHUTTLE MISSION STS-67 Final Report, 1-20 Mar. 1995

Gregory N. Katnik, Barry C. Bowen, and J. Bradley Davis Apr. 1995 101 p Original contains color illustrations
(NASA-TM-110651; NAS 1.15:110651) Avail: CASI HC A06/MF A02; 48 functional color pages

A debris/ice/thermal protection system assessment and integrated photographic analysis was conducted for Shuttle mission STS-67. Debris inspections of the flight elements and launch pad were performed before and after launch. Icing conditions on the External Tank were assessed by the use of computer programs and infrared scanner data during cryogenic loading of the vehicle, followed by on-pad visual inspection. High speed photography of the launch was analyzed to identify ice/debris sources and evaluate potential vehicle damage and/or in flight anomalies. This report documents the ice/debris/thermal protection (TPS) conditions and integrated photographic analysis of Shuttle mission STS-67, and the resulting effect on the Space Shuttle Program. Author

TASK 4 SUPPORTING TECHNOLOGY. PART 1: DETAILED TEST PLAN FOR LEADING EDGE TILE DEVELOPMENT. LEADING EDGE MATERIAL DEVELOPMENT AND TESTING

P. A. Hogenson, Paul Staszak, and Karrie Hinkle 30 May 1995 39 p
(Contract NCC8-79)
(NASA-CR-198633; NAS 1.26:198633; SSD95D0239-Pt-1) Avail: CASI HC A03/MF A01

This task develops two alternative candidate tile materials for leading edge applications: coated alumina enhanced thermal barrier (AETB) tile and silicone impregnated reusable ceramic ablator (SIRCA) tile. Upon reentry of the X-33/RLV space vehicle, the leading edges experience the highest heating rates and temperatures. The wing leading edge and nose cap experience peak temperatures in the range 2000 to 2700 F. Replacing reinforced carbon-carbon (RCC) with tile-based thermal protection system (TPS) materials is the primary objective. Weight, complexity, coating impact damage, and repairability are among the problems that this tile technology development addresses. The following subtasks will be performed in this development effort: tile coating development; SIRCA tile development; robustness testing of tiles; tile repair development; tile operations/processing; tile leading edge configuration; and life cycle testing. AN ANALYSIS OF ORBITAL PROPAGATORS FOR LOW EARTH ORBIT RENDEZVOUS M.S. Thesis
Kenneth R. Pollock Sep. 1994 57 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288883) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis examines the performance of three different orbital propagators to determine which provide the best performance for use in Low Earth Orbit Rendezvous. The performance evaluation is based upon the propagator's accuracy and the amount of time required to produce a solution. A Cowell high-fidelity propagator is used as a base line for comparison with an Encke and Clohessy-Wiltshire propagator. To further enhance the examination a Jacchia-70 atmospheric model and a GEM-9 Geopotential model are used to provide perturbing acceleration inputs to the propagators. All comparisons are performed in a Local Vertical, Local Horizontal Reference Frame with the target spacecraft at the coordinate center. Tainting of the input data set by a prior processor make the findings suspect. Findings support the prediction that while the Cowell propagator is the most accurate it also takes the most time to achieve results. Also, the Clohessy-Wiltshire, while taking the least time is the most inaccurate. The Encke propagator deliveries the most balanced result. DTIC

N95-28581 Office of Naval Research, Arlington, VA.
RADIO TELEMETRY BUOY FOR LONG-RANGE COMMUNICATION Patent Application
James D. Hagerty, inventor (to Navy) 11 Oct. 1994 18 p Filed 11 Oct. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-D017269; Navy-Case-75668; US-Patent-Appl-SN-322656) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A remotely controlled radio telemetry buoy serves as a communication link between an underwater acoustic interrogation/receiving transponder system and a remotely located surface platform. The buoy houses a transmission device, a transceiver device and a controller. The transmission device transmits data received from the transponder system as electromagnetic energy in a frequency range of 162-173 MHz. The transceiver device exchanges digital control signals between the surface platform and the buoy in the frequency range of 2-16 MHz. The controller transfers the control signals between the transceiver device and the transmission device and the transponder system. DTIC

A CLASS OF STABILIZING CONTROLLERS FOR FLEXIBLE MULTIBODY SYSTEMS
Suresh M. Joshi, Atul G. Kelkar, and Peiman G. Maghami May 1995 46 p
(RTOP 233-01-01-05)
(NASA-TP-3494; L-17413; NAS 1.60:3494) Avail: CASI HC A03/MF A01

The problem of controlling a class of nonlinear multibody flexible space systems consisting of a flexible central body to which a number of articulated appendages are attached is considered. Collocated actuators and sensors are assumed, and global asymptotic stability of such systems is established under a nonlinear dissipative control law. The stability is shown to be robust to unmodeled dynamics and parametric uncertainties. For a special case in which the attitude motion of the central body is small, the system, although still nonlinear, is shown to be stabilized by linear dissipative control laws. Two types of linear controllers are considered: static dissipative (constant gain) and dynamic dissipative. The static dissipative control law is also shown to provide robust stability in the presence of certain classes of actuator and sensor nonlinearities and actuator dynamics. The results obtained for this special case can also be readily applied for controlling single-body linear flexible space structures. For this case, a synthesis technique for the design of a suboptimal dynamic dissipative controller is also presented. The results obtained in this paper are applicable to a broad class of multibody and single-body systems such as flexible multilink manipulators, multipayload space platforms, and space antennas. The stability proofs use the Lyapunov approach and exploit the inherent passivity of such systems. Author

A PERSPECTIVE ON THE HUMAN-RATING PROCESS OF US SPACECRAFT: BOTH PAST AND PRESENT

George Zupp, ed. Apr. 1995 14 p Prepared in cooperation with NASA. Marshall Space Flight Center, Huntsville, AL; NASA. John F. Kennedy Space Center, Cocoa Beach, FL; NASA. John C. Stennis Space Center, Bay Saint Louis, MS

(NASA-SP-6104; S-798; NAS 1.21:6104) Avail: CASI HC A03/MF A01

The purpose of this report is to characterize the process of Human-Rating as employed by NASA for human spaceflight. An Agency-wide committee was formed in November 1992 to develop a Human-Rating Requirements Definition for Launch Vehicles based on conventional (historical) methods. The committee members were from NASA Headquarters, Marshall Space Flight Center, Kennedy Space Center, Stennis Space Center, and Johnson Space Center. After considerable discussion and analysis, committee members concluded that Human-Rating is the process of satisfying the mutual constraints of cost, schedule, mission performance, and risk while addressing the requirements for human safety, human performance, and human health management and care. ENGINEERING CALCULATIONS ASSOCIATED WITH THE ABLATIVE THERMAL PROTECTIVE STRUCTURES OF RETURNABLE SATELLITES

Lianqun Xing 17 Nov. 1994 24 p Transl. into ENGLISH from Zhongguo Kongjian Kexue Jishu (China), no. 2, 1991 p 26-34 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289593; NAIC-ID(RS)T-0004-93) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The paper describes one type of ablative thermal protective structure form associated with returnable satellites. It carries out discussions of ablation mechanisms and calculation methods associated with FL composite materials and silicone rubber. In conjunction with this, it carries out comparisons with flight tests and gives concluding opinions. DTIC

This document contains the abstracts from 63 papers published in support of the U.S. Air Force Phillips Laboratory Phase One Space Debris Research Program. This program, which was completed on 31 Dec 93, focused on characterizing the low earth orbit space debris environment and establishing the current and projected hazards to U.S. Air Force and Department of Defense space assets. The program emphasized both the measurement and modeling efforts needed to characterize the current debris environment for debris sizes down to 1 mm. In addition to the paper abstracts, this document lists paper titles, authors, and the paper publication sources. DTIC

OPTIMIZATION OF A NUTATION DAMPER ATTACHED TO A SPIN-STABILIZED SATELLITE M.S. Thesis

Brady P. Hauboldt Dec. 1994 67 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289424; AFIT/GSO/ENY/94D-2) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study uses linearized equations of motion for a rigid body with an attached spring-mass-damper to maximize the decay rate of a satellite's coning motion. An analysis of the numerical eigenvalues is presented which leads to an optimal relationship between relevant parameters: damper placement, spring constant, damping coefficient, system moments of inertia, and damper mass fraction. The coupled system's eigenvalues do not provide true critical damping, thus the real eigenvalue parts are minimized in order to achieve damping which requires the minimum amount of time. A comparison between this optimal design method and a classical method concludes with a noticeable improvement in damping performance for the optimized systems. DTIC

LONG-TERM VARIABILITY OF ELECTRON RADIATION DOSE IN GEOSYNCHRONOUS ORBIT Technical Report

H. C. Koons, D. J. Gorney, and J. B. Blake 30 Nov. 1994 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F04701-93-C-0094)

(AD-A289335; TR-93(3940)-13; SMC-TR-95-49) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A neural network that was developed to model the temporal variations of relativistic (greater than 3 MeV) electrons at geosynchronous orbit has been used to estimate the long-term variability of the radiation dose to geosynchronous spacecraft. The input to the neural network consists of 10 consecutive days of the daily sum of the planetary magnetic index Epsilon Kp. The output is an estimate of the daily-averaged electron flux for the tenth day. The model was used to compute the daily-averaged electron flux for energies greater than 3 MeV for each day from January 1933 through December 1988. Assuming that the average energy spectrum is independent of time, the annual radiation dose of electrons greater than 300 keV is obtained by scaling the model output to 300 keV and summing the daily-averaged flux for each year. The annual dose is found to vary from 0.25 to 0.4 times its average value. The dose is found to correlate only weakly with the annual mean sunspot number. The results are also applicable to studies of the effect on the middle atmosphere of the long-term variability of the precipitation of these electrons into the atmosphere. DTIC

CONTROL OF A LARGE SPACE STRUCTURE USING MULTIPLE MODEL ADAPTIVE ESTIMATION AND CONTROL TECHNIQUES M.S. Thesis

Gordon C. Griffin, Jr. Dec. 1994 249 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289309; AFIT/GE/ENG/94D-14) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A moving bank multiple model adaptive estimator/controller (MMAE/MMAC), based on linear system, quadratic cost, and Gaussian noise (LQG) assumptions, is used to quell unwanted vibrations in a large flexible space structure. The structure, known as the SPace Integrated Controls Experiment, or SPICE, exists at Phillips Laboratory, Kirtland AFB, NM. The structure consists of a large platform and a smaller platform connected by a tripod of flexible legs. The purpose of the control system is to maintain a very precise line-of-sight vector through the center of the spacecraft. Kalman filtering, used to estimate the position and velocity of the bending modes of the structure, and LQG control techniques are the primary design tools used in the MMAE/MMAC algorithms. Implementing a parallel bank of filters increases robustness when uncertainties exist in the system model, here specifically allowing adaptation to uncertain and changing undamped natural frequencies of the bending modes of the structure. A moving bank is used to reduce computational loading. The MMAE/MMAC design method provides an excellent method of estimating undamped natural frequency variations and quelling vibrations in the structure. The MMAE/MMAC was able to track numerous parameter changes and jumps while providing adequate control for the structure. DTIC

ANALYSIS OF MODAL BEHAVIOR AT FREQUENCY CROSS-OVER Final Report

Robert N. Costa, Jr. 28 Nov. 1994 250 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289304; AFIT/GA/ENY/94D-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The existence of the mode crossing condition is detected and analyzed in the Active Control of Space Structures Model 4 (ACOSS4). The condition is studied for its contribution to the inability of previous algorithms to successfully optimize the structure and converge to a feasible solution. A new algorithm is developed to detect and correct for mode crossings. The existence of the mode crossing condition is verified in ACOSS4 and found not to have appreciably affected the solution. The structure is then successfully optimized using new analytic methods based on modal expansion. An unrelated error in the optimization algorithm previously used is verified and corrected, thereby equipping the optimization algorithm with a second analytic method for eigenvector differentiation based on Nelson's Method. The second structure is the Control of Flexible Structures (COFS). The COFS structure is successfully reproduced and an initial eigenanalysis completed. DTIC

SATELLITE SURFACE MATERIAL COMPOSITION FROM SYNTHETIC SPECTRA M.S. Thesis

Eugene L. Caudill Dec. 1994 118 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289236; AFIT/GEO/ENP/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The objective of this research was to determine if measurements from a Sagnac interferometer could provide reliable estimates of satellite material composition. The Sagnac interferometer yields a spatial interferogram that can be sampled by a linear detector array. The interferogram is related to the spectrum of the source through a Fourier transform. Here, spectral reflectivities of nine common satellite materials were used to simulate the spectrum on obtains from an ideal Sagnac interferometer in the beam-train of a ground-based telescope whose mission is to view satellites. The signal-to-noise ratio of the spectrum was varied to simulate the effect of range variation between the sensor and the satellite. The simulated spectra consisted of a linear mixture of spectra from two of the nine materials. Three different architectures were developed and their performances compared. One of the three architectures consisted of nine artificial neural networks (ANN's), one for each material, and a linear estimator that estimated the satellite surface area attributable to each material. This method estimates the material composition by using a classifier to identify the materials contributing to the mixture, then eliminating unlikely contributors to the mixture before performing a constrained linear estimate. It is shown that due to high classification errors, the system using solely a linear estimator provides the estimate with the lowest errors. DTIC

A STATE-SPACE MODEL OF A LARGE, LIGHTLY DAMPED SPACE STRUCTURE USING THE EIGENSYSTEM REALIZATION ALGORITHM M.S. Thesis

Robert D. Woods Dec. 1994 166 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289251; AFIT/GA/ENY/94D-2) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Large, lightweight space structures of the future will require state-of-the-art vibration suppression systems. To design such a system, it is necessary to have a mathematical model that adequately describes the motion of the system. Coulomb damping compensation was utilized to remove a known nonlinearity from the frequency response functions obtained from the Passive and Active Control of Space Structures (PACOSS) Dynamic Test Article (DTA). Via the Eigensystem Realization algorithm (ERA), the frequency response functions were then used to generate a mathematical representation of the structure's dynamics. Two models were obtained. The first model, without friction compensation, acted as a baseline. The second was obtained using friction compensation. Comparing the models, it was determined that active friction compensation was worthwhile and resulted in a more accurate mathematical description of the system. DTIC

TELEPRESENT SPACECRAFT DOCKING WITH OBJECT-BASED BILATERAL CONTROL (OBBC) M.S. Thesis

Paul Woznick Dec. 1994 125 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289268; AFIT/GA/ENY/94D-9) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The concept of object-based control is extended to the field of teleoperation, specifically to accomplish the task of spacecraft docking via a bilateral manual controller. An object-based controller with bilateral feedback controls the motion of the grasped object, not the trajectory of the manipulator. For this reason it can be designed with feedback that is intricately linked with the task kinematics. The benefits derived from anthropomorphicity and force feedback are possible without kinematically/geometrically similar master-slave systems, complex calibration and joint mapping schemes, or expensive, high degree-of-freedom force reflection. Object-based control is ideal for low-level telerobotic interfaces. A hand controller and a spacecraft docking simulation are designed and constructed to demonstrate object-based bilateral control. The dominant task objective in spacecraft docking is the approach to a target vehicle along a single axis of motion. Several methods of bilateral feedback linked with this dominant objective are proposed in addition to simple force reflection. One method involves virtual forces and another utilizes velocity reflection. Each method, practical only with object-based control, enhance the man-machine interface by providing a heuristic method of control. DTIC

GENERIC SATELLITE MONITORING EXPERT SYSTEM M.S. Thesis

Loretta A. Kelemen Dec. 1994 133 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289209; AFIT/GSO/ENG/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Air Force Satellite Operations is undergoing major changes. Operators no longer receive detailed satellite training, instead they are taught basic fundamentals of satellite operations and expected to control multiple multimillion dollar satellites. The need is clear. An efficient and economical automated system is necessary to assist the satellite operator in the daily tasks of maintaining these DOD priority resources. Satellite intelligent controllers have been under R&D since the early 1980's to meet this need. These systems, however, have focused on the control of one constellation of satellites. In a military striving for efficiency and lower costs, developing a unique intelligent controller for each satellite constellation is unaffordable. This research provided support for the concept of a generic satellite intelligent controller, through the development of a prototype expert system. This capability would allow a generic rule-base to operate and maintain multiple satellite systems. The initial prototype detected anomalies on one subsystem of two different satellites. After the third satellite prototype was created, a third satellite was analyzed to show support for the viability of the satellite prototype. More research is necessary, but this thesis has created support for the concept of generic satellite controller and has laid the foundation for future extensions. DTIC

STRUCTURES AND MATERIALS TECHNOLOGY NEEDS FOR COMMUNICATIONS AND REMOTE SENSING SPACECRAFT Final Report, May 1994 - Mar. 1995

M. J. Gronet, G. A. Jensen, and J. W. Hoskins Apr. 1995 105 p
(Contract NAS1-19241; RTOP 233-01-01-02)
(NASA-CR-198166; NAS 1.26:198166) Avail: CASI HC A06/MF A02

This report documents trade studies conducted from the perspective of a small spacecraft developer to determine and quantify the structures and structural materials technology development needs for future commercial and NASA small spacecraft to be launched in the period 1999 to 2005. Emphasis is placed on small satellites weighing less than 1800 pounds for two focus low-Earth orbit missions: commercial communications and remote sensing. The focus missions are characterized in terms of orbit, spacecraft size, performance, and design drivers. Small spacecraft program personnel were interviewed to determine their technology needs, and the results are summarized. A systems-analysis approach for quantifying the benefits of inserting advanced state-of-the-art technologies into a current reference, state-of-the-practice small spacecraft design is developed and presented. This approach is employed in a set of abbreviated trade studies to quantify the payoffs of using a subset of 11 advanced technologies selected from the interview results The 11 technology development opportunities are then ranked based on their relative payoff. Based on the strong potential for significant benefits, recommendations are made to pursue development of 8 and the 11 technologies. Other important technology development areas identified are recommended for further study. Author

RAREFIED GAS EFFECTS ON AEROBRAKING/REENTRY VEHICLES WITH WAKES Final Report
Amolak C. Jain 28 Feb. 1995 93 p
(Contract NAS8-39368; SBIR-02.04-8581)
(NASA-CR-196586; NAS 1.26:196586; RTR-249-01) Avail: CASI HC A05/MF A01

The purpose of the present investigation is to understand the basic nature of the wake flow behind an Aeroassisted Space Transfer Vehicle (ASTV) or Aeroassisted Flight Experiment Vehicle (AFE). The astronauts were supposed to fly in the bay of an ASTV or AFE. This problem of thermal environment on the bay of the vehicle becomes important to ensure the safety of the astronauts. A computer code based on the full Navier-Stokes equations with surface slip and temperature jump boundary conditions is developed. The governing equations are expressed in spherical-cylindrical coordinates and a third order accurate upwind-biased scheme with provision to use a second order accurate central-difference scheme of numerical integration, is used. To ensure a high order of accuracy, complete flowfield from the stagnation line to the wake flow is computed. For this purpose, the computer code is divided into three parts, viz., stagnation part, forepart and aftpart and has the provision to converge each part to provide boundary conditions to the next part or we can compute the entire flow in each iteration. Extensive numerical computations have been carried out for a number of prescribed conditions, but for the sake of brevity, the results of computations for SR3 tunnel conditions of CNRS, France, are reported here. Computations have been carried out on a cylindrical body with a spherical nose (also called sphere-cylinder body) and on a hemisphere with a cylindrical bay with radius equal to a quarter of the radius of the base of hemisphere, to simulate a generic AFE configuration. Comparison of the results on sphere-cylinder and on the generic AFE body helps us to understand the rarefaction effects and the effect of wake flow on the main flowfield. Comparison with the DSMC data from NASA LaRC indicates general agreement about the nature of wake, but our results differ quantitatively with the DSMC results. At the present moment, the results from the CNRS tunnel are not available. As such, a quantitative comparison of the present results with the experimental data is not possible. In general, it is found that the wake on a generic AFE is a slow moving, high temperature, low density and, consequently, low pressure fluid. Author

A MULTI-ATTRIBUTE-UTILITY-THEORY MODEL THAT MINIMIZES INTERVIEW-DATA REQUIREMENTS: A CONSOLIDATION OF SPACE LAUNCH DECISIONS M.S. Thesis
Raymond W. Staats Dec. 1994 123 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289421; AFIT/GSO/ENS/94D-15) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research uses multi-attribute utility theory (MAUT) to define a mathematical representation of a decision maker's utility associated with a satellite system. While developing the survey instrument, we focused on making it simpler to administer, primarily by eliminating the use of lottery questions. These simplifications enabled us to shorten our interview with the decision maker to under two hours for a rather complex model. The MAUT model gives National Air Intelligence Center (NAIC) analysts the ability to rank order satellite systems using the common measurement scale of 'utiles.' This tool allows a meaningful comparison of vastly different satellites. Properly prioritized launch of space assets will be key to maintaining our capabilities in the long term. The ordering methodology of this model was extended to a multi-criterion optimization (MCO) problem to demonstrate its potential use in prioritizing and scheduling limited launch resources. The results of these two case studies and the MCO application are combined to develop some characterizations of a theoretical group utility function. Most complex decisions are made by groups rather than by an individual. This research concludes with some insights on the impact of an individual's preferences on a decision that is ultimately made by the group. DTIC

STATIC STABILITY OF A THREE-DIMENSIONAL SPACE TRUSS M.S. Thesis - Case Western Reserve Univ., 1994
John F. Shaker May 1995 114 p
(RTOP 478-42-10)
(NASA-TM-106944; E-9679; NAS 1.15:106944) Avail: CASI HC A06/MF A02

In order to deploy large flexible space structures it is necessary to develop support systems that are strong and lightweight. The most recent example of this aerospace design need is vividly evident in the space station solar array assembly. In order to accommodate both weight limitations and strength performance criteria, ABLE Engineering has developed the Folding Articulating Square Truss (FASTMast) support structure. The FASTMast is a space truss/mechanism hybrid that can provide system support while adhering to stringent packaging demands. However, due to its slender nature and anticipated loading, stability characterization is a critical part of the design process. Furthermore, the dire consequences surely to result from a catastrophic instability quickly provide the motivation for careful examination of this problem. The fundamental components of the space station solar array system are the (1) solar array blanket system, (2) FASTMast support structure, and (3) mast canister assembly. The FASTMast once fully deployed from the canister will provide support to the solar array blankets. A unique feature of this structure is that the system responds linearly within a certain range of operating loads and nonlinearly when that range is exceeded. The source of nonlinear behavior in this case is due to a changing stiffness state resulting from an inability of diagonal members to resist applied loads. The principal objective of this study was to establish the failure modes involving instability of the FASTMast structure. Also of great interest during this effort was to establish a reliable analytical approach capable of effectively predicting critical values at which the mast becomes unstable. Due to the dual nature of structural response inherent to this problem, both linear and nonlinear analyses are required to characterize the mast in terms of stability. The approach employed herein is one that can be considered systematic in nature. The analysis begins with one and two-dimensional failure models of the system and its important components. From knowledge gained through preliminary analyses a foundation is developed for three-dimensional analyses of the FASTMast structure. The three-dimensional finite element (FE) analysis presented here involves a FASTMast system one-tenth the size of the actual flight unit. Although this study does not yield failure analysis results that apply directly to the flight article, it does establish a method by which the full-scale mast can be evaluated. Author

DESIGN OF A UNIDIRECTIONAL COMPOSITE MOMENTUM WHEEL RIM
Bradley Shogrin (Case Western Reserve Univ., Cleveland, OH.), William R. Jones, Jr., and Joseph M. Prahl (Case Western Reserve Univ., Cleveland, OH.) May 1995 28 p
(RTOP 274-00-00)
(NASA-TM-106911; E-9613; NAS 1.15:106911) Avail: CASI HC A03/MF A01

A preliminary study comparing twelve unidirectional-fiber composite systems to five metal materials conventionally used in momentum wheels is presented. Six different fibers are considered in the study: E-Glass, S-Glass, Boron, AS, T300, and Kevlar. Because of the possibility of high momentum requirements, and thus high stresses, only two matrix materials are considered: a high-modulus (HM) and a intermediate-modulus-high-strength (IMHS) matrix. Each of the six fibers are coupled with each of the two matrix materials. In an effort to optimize the composite system, each composite is considered while varying the fiber volume ratio from 0.0 to 0.7 in increments of 0.1. For fiber volume ratios above 0.2, all twelve unidirectional-fiber composite systems meet the study's requirements with higher factors of safety and less mass than the five conventional isotropic (metal) materials. For example, at a fiber volume ratio of 0.6, the Kevlar/IMHS composite system has a safety factor 4.5 times greater than that of a steel (maraging) system and an approximately 10 percent reduction in weight. The present invention is directed to methods and apparatus relating to design, construction, integration and assembly of a space station. The present invention uses pre-integrated open (unpressurized) truss segments for modular construction of the space station. Each segment includes a truss structure and utility subsystem which may be fully assembled and tested on Earth. The segments may be latched together on orbit using a remote latching system. Utility subsystems, such as solar panels and radiators, are pre-integrated into the appropriate truss segment, and are deployable from the respective truss segment on orbit. Rails run lengthwise along the assembled truss. The rails may be used with a mobile transporter for translating truss segments with respect to the spacecraft as part of the space station assembly process. The rails may also be used with a mobile transporter for carrying crew personnel, a robotic arm, and other equipment. With the present invention, the EVA time required for assembly as Space Station Freedom is markedly reduced.

PANSAT is a small, spread-spectrum, communications satellite under design at the Naval Postgraduate School. It will support a store and forward bulletin board system for use by the amateur radio community. The flight software is responsible for the autonomous telemetry collection and hardware control operations of the satellite, communications and file transfer protocols allowing access to the bulletin board system, and command interpretation and response to ground control commands. in this thesis, the complete flight software architecture and module interfaces are specified using the Estelle Format Description Technique. The module bodies dealing with communications and file transfer protocols are specified in detail in Estelle. The current design goat for the remainder of the flight software modules are discussed. Appendices include the preliminary flight software specification itself, a data flow diagram interpretation of the specification, and a summary of the Estelle syntax used. DTIC

The HIPES Program was conducted for NASA-LeRC by TRW. The Basic Program consisted of system studies, design of testbed engine, fabrication and testing of engine. Studies of both pressure-fed and pump-fed systems were investigated for N2O4 and both MMH and N2H4 fuels with the result that N2H4 provides the maximum payload for all satellites over MMH. The higher pressure engine offers improved performance with smaller envelope and associated weight savings. Pump-fed systems offer maximum payload for large and medium weight satellites while pressure-fed systems offer maximum payload for small light weight satellites. The major benefits of HIPES are high performance within a confined length maximizing payload for lightsats which are length (volume) constrained. Three types of thrust chambers were evaluated -- Copper heatsink at 400, 500 and 600 psia chamber pressures for performance/thermal; water cooled to determine heat absorbed to predict rhenium engine operation; and rhenium to validate the concept. The HIPES engine demonstrated very high performance at 50 lbf thrust (epsilon = 150) and Pc = 500 psia with both fuels: Isp = 337 sec using N2O4-N2H4 and ISP = 327.5 sec using N2O4-MMH indicating combustion efficiencies greater than 98%. A powder metallurgy rhenium engine demonstrated operation with high performance at Pc = 500 psia which indicated the viability of the concept. Author (revised)

PLUME MEASUREMENTS WITH THE T5 XENON ION THRUSTER
James E. Pollard 30 Sep. 1994 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts F04701-93-C-0094; F04701-88-C-0089)
(AD-A288697; TR-94(4507)-2; SMC-TR-94-44) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Two measurement techniques for investigating performance and life-limiting characteristics of ion engines are applied to a 10 cm T5 xenon thruster: (1) Thrust vector stability is evaluated with four double-wire Langmuir probes, aligned in the form of a cross, which are placed in the exhaust plume and are translated by a motorized positioning system to balance the currents collected along two orthogonal axes. The thrust vector position is thereby tracked with an angular resolution of less than 0.01 deg and a response time of less than 5 s. (2) A plume-sampling mass spectrometer has been developed for measuring the xenon charge state distribution and the flux of erosion products from the discharge chamber as a function of operating point. To demonstrate the capability for real-time erosion monitoring, plume spectra that reveal trace amounts of metal ions are presented. DTIC

DEVELOPMENT TEST OF A LIQUID APOGEE ENGINE FOR THE ETS-6
Oct. 1994 25 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1250) Avail: CASI HC A03/MF A01

A pressure-fed, full-blowdown, nitrogen tetroxide (NTO)/hydrazine (N2H4) bipropellant liquid apogee propulsion system was selected for engineering test satellite - VI (ETS-VI), a 2000-kg Japanese engineering test satellite. This 2000-kg mass geostationary satellite is scheduled to be launched by an H-II rocket in 1994. The apogee engine required a high reliability and relatively high performance for a pressure fed system. In the preliminary development phase of the apogee engine, a peak vacuum specific impulse Ispv of 325 s was set as the initial development target. This performance requirement of the apogee engine is greater than that of the bipropellant engine using NTO/monomethyl hydrazine (MMH). To meet such high performance requirements, the authors employed a NTO/N2H4 propellant system instead of NTO/MMH propellant and used a very large area ratio nozzle (nozzle area ratio is 200 to 300). To enhance the reliability of the apogee propulsion system, we selected a pressure-fed, full-blowdown system. Fundamental studies including hard-start, pop and thermal problems were also conducted during the development series of apogee engine started in 1983. Performance characteristics of apogee engine developed in 1990 were as follows: chamber pressure Pc = 0.97 approximately 0.63 MPa, mixture ratio MR = 0.85 approximately 1.05, vacuum thrust = 1980 approximately 1280 N, mean vacuum specific impulse Ispv = 320.0 +- 2.7 s, and total burn time = 2900 s. Delivered peak Ispv was less than the initial development target, however, the engine performance was higher than that of the engine for NTO/MMH propellant. This paper describes mainly the development studies of the injectors used in the apogee engine. Author

INVESTIGATION OF BOUNDARY LAYER AND PERFORMANCE EFFECTS OF TRANSPIRATION COOLING THROUGH A POROUS PLATE IN A ROCKET NOZZLE M.S. Thesis
David N. Keener Dec. 1994 116 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289393; AFIT/GA/ENY/94D-3) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study used a range of low blowing ratios with air through an area of porous material in a Mach 2.0 nozzle to quantity the change in boundary layer thickness as a function of blowing ratio. Also, exit and wall Mach number profiles at each blowing ratio were collected to characterize performance losses as a result of blowing. Performance in terms of specific impulse was also studied. As expected, the boundary layer thickness increased and nozzle performance in terms of exit Mach number decreased with increasing blowing ratio. DTIC

EFFECTS OF BLOWING RATIO ON HEAT TRANSFER TO THE THROAT REGION OF A POROUS-WALLED NOZZLE Final Report
Joseph L. Lenertz Dec. 1994 108 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289459; AFIT/GA/ENY/94D-7) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This experiment analyzed the effects of blowing ratio on heat transfer to the throat region of a porous-walled nozzle, using the AFIT low speed shock tube. Heat flux data were taken from both sides of a two-dimensional Mach 2.0 (Re/m = 5.2 x 10(exp 7) nozzle using thin film resistance thermometers. One side was transpiration-cooled by secondary air injection through a sintered wall, while the other side served as a control. Control results were validated using empirical relations, and cooled side results showed up to a 14% reduction in heat transfer coefficient at blowing ratios of only 0.51%. The linear nature of cooling effectiveness at these low blowing ratios allowed a modification of nozzle heat transfer equations to include a blowing ratio parameter. Disturbance of primary flow was also minimized, causing no measurable reduction of nozzle performance. DTIC

A REVIEW OF NICKEL HYDROGEN BATTERY TECHNOLOGY
John J. Smithrick and Patricia M. ODonnell May 1995 10 p Presented at the 30th Intersociety Energy Conversion Engineering Conference, Orlando, FL, 31 Jul. - 4 Aug. 1995; cosponsored by ASME, IEEE, AIChE, ANS, ACS and AIAA
(RTOP 233-01-0B)
(NASA-TM-106918; E-9626; NAS 1.26:106918; ASME-95-367) Avail: CASI HC A02/MF A01

This paper on nickel hydrogen batteries is an overview of the various nickel hydrogen battery design options, technical accomplishments, validation test results and trends. There is more than one nickel hydrogen battery design, each having its advantage for specific applications. The major battery designs are individual pressure vessel (IPV), common pressure vessel (CPV), bipolar and low pressure metal hydride. State-of-the-art (SOA) nickel hydrogen batteries are replacing nickel cadmium batteries in almost all geosynchronous orbit (GEO) applications requiring power above 1 kW. However, for the more severe low earth orbit (LEO) applications (greater than 30,000 cycles), the current cycle life of 4000 to 10,000 cycles at 60 percent DOD should be improved. A NASA Lewis Research Center innovative advanced design IPV nickel hydrogen cell led to a breakthrough in cycle life enabling LEO applications at deep depths of discharge (DOD). A trend for some future satellites is to increase the power level to greater than 6 kW. Another trend is to decrease the power to less than 1 kW for small low cost satellites. Hence, the challenge is to reduce battery mass, volume and cost. A key is to develop a light weight nickel electrode and alternate battery designs. A common pressure vessel (CPV) nickel hydrogen battery is emerging as a viable alternative to the IPV design. It has the advantage of reduced mass, volume and manufacturing costs. A 10 Ah CPV battery has successfully provided power on the relatively short lived Clementine Spacecraft. A bipolar nickel hydrogen battery design has been demonstrated (15,000 LEO cycles, 40 percent DOD). The advantage is also a significant reduction in volume, a modest reduction in mass, and like most bipolar designs, features a high pulse power capability. A low pressure aerospace nickel metal hydride battery cell has been developed and is on the market. It is a prismatic design which has the advantage of a significant reduction in volume and a reduction in manufacturing cost. Author

The computation of flows within interconnected, multiple-disk cavities shows strong interaction between the cavities and the power stream. For this reason, simulations of single cavities in such cases are not realistic; the complete, linked configuration must be considered. Unsteady flow fields affect engine stability and can engender power-stream-driven secondary flows that produce local hot spotting or general cavity heating. Further, a concentric whirling rotor produces a circumferential pressure wave, but a statically eccentric whirling rotor produces a radial wave; both waves affect cavity ingestion and the stability of the entire engine. It is strongly suggested that seals be used to enhance turbojet engine stability. Simple devices, such as swirl brakes, honeycomb inserts, and new seal configurations, should be considered. The cost effectiveness of the NASA Lewis Research Center seals program can be expressed in terms of program goals (e.g., the Integrated High-pressure/Temperature Engine Technology (IHPTET) cannot be achieved without such a program), cost (savings to $250 million/1-percent decrease in specific fuel consumption), and indirect benefits (reduction of atmospheric NO(x) and CO2 and reduction of powerplant downtime). Solar electric propulsion (SEP) technology is already being used for geostationary satellite stationkeeping to increase payload mass. By using this same technology to perform part of the orbit transfer additional increases in payload mass can be achieved. Advanced chemical and N2H4 arcjet systems are used to increase the payload mass by performing stationkeeping and part of the orbit transfer. Four mission options are analyzed which show the impact of either sharing the orbit transfer between chemical and SEP systems or having either complete the transfer alone. Results show that for an Atlas 2AS payload increases in net mass (geostationary satellite mass less wet propulsion system mass) of up to 100 kg can be achieved using advanced chemical for the transfer and advanced N2H4 arcjets for stationkeeping. An additional 100 kg can be added using advanced N2H4 arcjets for part of a 40 day orbit transfer. Author

DIRECT DRIVE OPTIONS FOR ELECTRIC PROPULSION SYSTEMS
John A. Hamley May 1995 8 p Presented at the 30th Intersociety Energy Conversion Engineering Conference, Orlando, FL, 31 Jul. - 4 Aug. 1995; cosponsored by ASME, IEEE, AIChE, ANS, ACS, and AIAA
(RTOP 242-70-02)
(NASA-TM-106576; E-9618; NAS 1.15:106576; AIAA Paper 95-364) Avail: CASI HC A02/MF A01

Power processing units (PPU's) in an electric propulsion system provide many challenging integration issues. The PPU must provide power to the electric thruster while maintaining compatibility with all of the spacecraft power and data systems. Inefficiencies in the power processor produce heat, which must be radiated to the environment in order to ensure reliable operation. Although PPU efficiencies are generally greater than 0.9, heat loads are often substantial. This heat must be rejected by thermal control systems which generally have specific masses of 15-30 kg/kW. PPU's also represent a large fraction of the electric propulsion system dry mass. Simplification or elimination of power processing in a propulsion system would reduce the electric propulsion system specific mass and improve the overall reliability and performance. A direct drive system would eliminate all or some of the power supplies required to operate a thruster by directly connecting the various thruster loads to the solar array. The development of concentrator solar arrays has enabled power bus voltages in excess of 300 V which is high enough for direct drive applications for Hall thrusters such as the Stationary Plasma Thruster (SPT). The option of solar array direct drive for SPT's is explored to provide a comparison between conventional and direct drive system mass. Author

Ignition testing of hollow cathode assemblies being developed for the Space Station plasma contactor system has been initiated to validate reliable multiple restart capability. An ignition approach was implemented that was derived from an earlier arcjet program that successfully demonstrated over 11,600 ignitions. For this, a test profile was developed to allow accelerated cyclic testing at expected operating conditions. To date, one hollow cathode assembly has been used to demonstrate multiple ignitions. A prototype hollow cathode assembly has achieved 3,615 successful ignitions at a nominal anode voltage of 18.0 V. During the ignition testing several parameters were investigated, of which the heater power and pre-heat time were the only parameters found to significantly impact ignition rate. Author

MICRO ELECTRIC PROPULSION FEASIBILITY Final Report
Graeme Aston and Martha Aston Nov. 1992 74 p
(Contract NAS3-26062; RTOP 506-42-31)
(NASA-CR-189139; E-7428; NAS 1.26:189139) Avail: CASI HC A04/MF A01

Miniature, 50 kg class, strategic satellites intended for extended deployment in space require an on-board propulsion capability to perform needed attitude control adjustments and drag compensation maneuvers. Even on such very small spacecraft, these orbit maintenance functions can be significant and result in a substantial propellant mass requirement. Development of advanced propulsion technology could reduce this propellant mass significantly, and thereby maximize the payload capability of these spacecraft. In addition, spacecraft maneuverability could be enhanced and/or multi-year mission lifetimes realized. These benefits cut spacecraft replacement costs, and reduce services needed to maintain the launch vehicles. For SDIO brilliant pebble spacecraft, a miniaturized hydrazine propulsion system provides both boost and divert thrust control. This type of propulsion system is highly integrated and is capable of delivering large thrust levels for short time periods. However, orbit maintenance functions such as drag make-up require only very small velocity corrections. Using the boost and/or divert thrusters for these small corrections exposes this highly integrated propulsion system to continuous on/off cycling and thereby increases the risk of system failure. Furthermore, since drag compensation velocity corrections would be orders of magnitude less than these thrusters were designed to deliver, their effective specific impulse would be expected to be lower when operated at very short pulse lengths. The net result of these effects would be a significant depletion of the on-board hydrazine propellant supply throughout the mission, and a reduced propulsion system reliability, both of which would degrade the interceptors usefulness. In addition to SDIO brilliant pebble spacecraft, comparably small spacecraft can be anticipated for other future strategic defense applications such as surveillance and communication. For such spacecraft, high capability and reliability, minimal detectability and low cost are requirements. All these miniature spacecraft share a common characteristic: because of their on-board electronic equipment they have, by design, solar order 50-100 W. In a relative sense, such spacecraft are power rich when compared to other larger spacecraft. This power rich situation is offset by very tight mass budgets, which make reductions in propellant mass requirements a key issue in meeting overall spacecraft minimum mass goals. In principle, power rich and propellant poor brilliant pebbles class spacecraft can benefit from using high specific impulse electric propulsion to reduce chemical propellant mass requirements. However, at power levels of order 50 W, arcjets cannot be made to function, ion thrusters are too complex and heavy and resistojets have too low a specific impulse. Recognizing these capability limitations in existing electric propulsion technology, the SDIO/IST sponsored the Phase I SBIR Micro Electric Propulsion (MEP) thruster study described in this report. The objective of this study was to examine the feasibility of developing a very simple, low mass and small volume, electric thruster for operation on hydrazine at less than 100 W of input power. The feasibility of developing such a MEP thruster was successfully demonstrated by EPL by the discovery of a novel plasma acceleration process. The sections in this report summarize the approach, test results and major accomplishments of this proof-of-concept program. Author

ANALYSIS OF SOLAR RECEIVER FLUX DISTRIBUTIONS FOR US/RUSSION SOLAR DYNAMIC SYSTEM DEMONSTRATION ON THE MIR SPACE STATION

Thomas W. Kerslake and James Fincannon Jun. 1995 8 p Presented at the 30th Intersociety Energy Conversion Engineering Conference, Orlando, FL, 31 Jul. - 1 Aug. 1995
(RTOP 547-10-11)
(NASA-TM-106933; E-9660; NAS 1.15:106933; IECEC-95-136) Avail: CASI HC A02/MF A01

The United States and Russia have agreed to jointly develop a solar dynamic (SD) system for flight demonstration on the Russian MIR space station starting in late 1997. Two important components of this SD system are the solar concentrator and heat receiver provided by Russia and the U.S., respectively. This paper describes optical analysis of the concentrator and solar flux predictions on target receiver surfaces. The optical analysis is performed using the code CIRCE2. These analyses account for finite sun size with limb darkening, concentrator surface slope and position errors, concentrator petal thermal deformation, gaps between petals, and the shading effect of the receiver support struts. The receiver spatial flux distributions are then combined with concentrator shadowing predictions. Geometric shadowing patterns are traced from the concentrator to the target receiver surfaces. These patterns vary with time depending on the chosen MIR flight attitude and orbital mechanics of the MIR spacecraft. The resulting predictions provide spatial and temporal receiver flux distributions for any specified mission profile. The impact these flux distributions have on receiver design and control of the Brayton engine are discussed. Author

The NASA Lewis Research Center is currently working with RSC-Energia, the Russian Space Agency, and Allied Signal in developing a flight demonstration solar dynamic power system. This type of power system is dependent upon solar flux that is reflected and concentrated into a thermal storage system to provide the thermal energy input to a closed-cycle Brayton heat engine. The solar dynamic unit will be flown on the Russian Mir space station in anticipation of use on the International Space Station Alpha. By the time the power system is launched, the Mir will be a spatially complex configuration which will have, in addition to the three-gimbaled solar dynamic unit, eleven solar array wings that are either fixed or track the Sun along one axis and a variety or repositionable habitation and experiment modules. The proximity of arrays to modules creates a situation which makes it highly probable that there will be varying solar flux due to shadowing on the solar dynamic unit and some of the arrays throughout the orbit. Shadowing causes fluctuations in the power output from the arrays and the solar dynamic power system, thus reducing the energy capabilities of the spacecraft. An assessment of the capabilities of the power system under these conditions is an important part in influencing the design and operations of the spacecraft and predicting its energy performance. This paper describes the results obtained from using the Orbiting Spacecraft Shadowing Analysis Station program that was integrated into the Station Power Analysis for Capability Evaluation (SPACE) electrical power system computer program. OSSA allows one to consider the numerous complex factors for analyzing the shadowing effects on the electrical power system including the variety of spacecraft hardware geometric configurations, yearly and daily orbital variations in the vehicle attitude and orbital maneuvers (for communications coverage, payload pointing requirements and rendezvous/docking with other vehicles). The geometric models of the MIR with a solar dynamic power unit that were used in performing shadowing analyses are described. Also presented in this paper are results for individual orbits for several flight attitude cases which include assessments of the shadowing impacts upon the solar dynamic unit and the solar arrays. These cases depict typical MIR flight attitudes likely to have shadowing impact. Because of the time varying nature of the Mir orientation with respect to the Sun and the lack of knowledge of the precise timing of the attitude changes, strategies must be devised to assess and depict the shadowing impacts on power generation throughout the year. To address this, the best, nominal and worst impacts of shadowing considering a wide possible range of parameter changes for typical mission operation period are shown. Author

DEVELOPMENTAL PROBLEMS AND THEIR SOLUTION FOR THE SPACE SHUTTLE MAIN ENGINE ALTERNATE LIQUID OXYGEN HIGH-PRESSURE TURBOPUMP: ANOMALY OR FAILURE INVESTIGATION THE KEY

R. Ryan and L. A. Gross Washington May 1995 79 p
(NASA-TP-3553; M-780; NAS 1.60:3553) Avail: CASI HC A05/MF A01

The Space Shuttle main engine (SSME) alternate high-pressure liquid oxygen pump experienced synchronous vibration and ball bearing life problems that were program threatening. The success of the program hinged on the ability to solve these development problems. The design and solutions to these problems are engirded in the lessons learned and experiences from prior programs, technology programs, and the ability to properly conduct failure or anomaly investigations. The failure investigation determines the problem cause and is the basis for recommending design solutions. For a complex problem, a comprehensive solution requires that formal investigation procedures be used, including fault trees, resolution logic, and action items worked through a concurrent engineering-multidiscipline team. The normal tendency to use an intuitive, cut-and-try approach will usually prove to be costly, both in money and time and will reach a less than optimum, poorly understood answer. The SSME alternate high-pressure oxidizer turbopump development has had two complex problems critical to program success: (1) high synchronous vibrations and (2) excessive ball bearing wear. This paper will use these two problems as examples of this formal failure investigation approach. The results of the team's investigation provides insight into the complexity of the turbomachinery technical discipline interacting/sensitivities and the fine balance of competing investigations required to solve problems and guarantee program success. It is very important to the solution process that maximum use be made of the resources that both the contractor and Government can bring to the problem in a supporting and noncompeting way. There is no place for the not-invented-here attitude. The resources include, but are not limited to: (1) specially skilled professionals; (2) supporting technologies; (3) computational codes and capabilities; and (4) test and manufacturing facilities. THE 1994 JANNAF SAFETY AND ENVIRONMENTAL PROTECTION SUBCOMMITTEE MEETING, VOLUME 1
Lorri A. Pickett, ed. Aug. 1994 442 p Meeting held in San Diego, CA, 1-4 Aug. 1994
(Contract N00014-91-C-0001)
(CPIA-Publ-614-Vol-1) Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

This publication contains thirty-nine technical papers and progress reports presented at the 1994 Joint Army-Navy-NASA-Air Force (JANNAF) Safety and Environmental Protection Subcommittee (S&EPS) Meeting held 1-4 August 1994 at the Town & Country Hotel, San Diego, California. Topics covered include: toxic vapor detection methods; hazardous waste management and waste minimization techniques; occupational safety and industrial hygiene issues; explosives safety; reclamation, disposal, and demilitarization methods; and environmental impacts associated with propulsion and ordnance related operations. The proceedings are published in two volumes. Volume 2 contains four papers limited in distribution. For individual titles, see N95-28295 through N95-28326.

This paper describes how industry was persuaded to protect the ozone layer and how engineers contributed to the success. It describes the voluntary and cooperative efforts of industry to speed protection of the ozone layer and it explains the U.S. EPA strategy for technical cooperation with developing countries which involves government/industry partnerships and project leadership companies. Some of most critical remaining uses of ozone-depleting solvents are for rocket motor manufacturing, operation, and refurbishment. Propulsion systems engineers are key to developing and implementing alternatives and substitutes to these uses. Author (revised)

OB/OD TREATMENT: THE EFFECTIVE USE OF MEASURED FIELD DATA AND AIR MODELING TO SUPPORT AN ENVIRONMENTAL ASSESSMENT **c45**
T. J. Tope, H. C. Simmons, and W. F. Howell *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 13-22 (For primary document see N95-28294 09-20)
(Contract DACW05-92-D-0016)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The most commonly used treatment and disposal method for managing unserviceable conventional munition wastes generated by Department of Defense (DOD) installations is open burning/open detonation (OB/OD). Regulatory constraints over the past decade, however, have reduced and limited the accessibility and frequency of OB/OD activities. Impeding the acceptance of OB/OD by regulators and the public is the lack of credible and valid data that may be used in an environmental assessment to support OB/OD as a treatment and disposal method that does not impact human health and the environment. This paper presents the technical approach and results for the air environmental assessments performed to support permitting of OB/OD facilities at three Air Force installations. In general these assessments include calculating the worst case airborne concentrations from OB/OD treatment at the nearest off-site receptor and demonstrating these concentrations pose no adverse human health risk. This is accomplished through the use of emission factors developed through BangBox testing, air dispersion modeling, and comparison of worst-case modeling results with federal and state limitations on criteria and non-criteria air pollutant emissions. The results of the assessment demonstrate that no adverse impacts to human health would occur as result of the OB/OD activities performed at these Air Force installations. Author

EVALUATING THE ENVIRONMENTAL VIABILITY OF OPEN BURNING/OPEN DETONATION OPERATIONS **c45**
MacDonald B. Johnson and Douglass P. Bacon (Energy Conversion Corp., Salt Lake City, UT.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 23-31 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Despite their historical record of safety and efficiency, open burning/open detonation (OB/OD) operations now face serious questions about their suitability for destroying propellants, energetic munitions, and energetic wastes. Environmental regulators are demanding emissions data to support applications for OB/OD permits submitted under provisions of the Resource Conservation and Recovery Act (RCRA) subpart X. Until recent development of the BangBox testing system, no means existed for obtaining these data. This paper describes the evolution of the integrated testing system (consisting of personnel, instrument and equipment, procedures, and facilities), successful audits conducted by the U.S. Environmental Agency (USEPA), and application of results. The system's development and its technologies are significant because there is no other method which can accurately and credibly characterize OB/OD combustion products. Of particular interest is that volatile and semivolatile organic compounds resulting from OB/OD of propellants, explosives, and energetic munitions are proving to be far below levels of environmental concern and do not pose a threat to health or the environment. USE OF MUSSELS IN BIOMONITORING OF ENVIRONMENTAL IMPACTS OF PROPELLANTS, PROJECTILES, EXPLOSIVES, AND PYROTECHNICS **c51**
J. Hixson, R. Jennings, and C. H. Stagg (Joint Readiness Training Center, Fort Polk, LA.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 33-42 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The primary mission of the Ft. Polk Military Reservation is to provide a base of operations for the Joint Readiness Training Center (JRTC). Army and Air Force contingency forces conduct joint training operations at the JRTC which replicate, as closely as possible, those of real low- and mid-intensity conflicts. The reservation operates an open burning/open detonation (OB/OD) unit primarily to treat unserviceable ammunition and explosives generated as a result of routine training operations. The unit is located in a national forest, and consequently there has been concern regarding potential impacts of OB/OD activities on wildlife. The U.S. Forest Service (the site owner) requested that an environmental assessment be performed for the unit to evaluate these potential impacts. The entire military reservation, including the OB/OD unit, is located in an area with numerous wetlands and streams. Based on a prior investigation of limited scope, there was some concern that activities at the reservation may have adversely impacted aquatic invertebrates. It was decided that a biomonitoring study should be conducted to clarify the results of the previous investigation and to determine the contribution of the activities on the reservation to downstream population effects. The biomonitoring study was designed to be performed in two stages. The first stage, discussed in this paper, was a screening analysis to determine whether specific chemicals were present in mussels within and downstream of the reservation. This stage will be followed with a more detailed analysis including population studies as well as chemical analyses of biota collected from multiple locations. Author

BIODEGRADATION OF NITRATE ESTERS **c25**

Johnathan R. Stacy, M. K. Speedie (Maryland Univ., Baltimore, MD.), L. Geelhaar (Maryland Univ., Baltimore, MD.), Min Meng (Maryland Univ., Baltimore, MD.), Gregory Payne (Maryland Univ. Baltimore County, Catonsville, MD.), W. Q. Sun (Maryland Univ. Baltimore County, Catonsville, MD.), Anemi Patal (Maryland Univ. Baltimore County, Catonsville, MD.), and Rakesh Govind (Cincinnati Univ., OH.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 43-50 (For primary document see N95-28294 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The development of biological treatment methods for nitrate ester contaminated soil and water will be discussed. The approach is to develop existing biological treatment methods for use with nitrate ester contaminated soil and water. These methods would be applied using existing and commonly used engineering methods. The advantage to the multi-technique approach is that it would address sites with different problems and characteristics. Technologies for water treatment address ground water contamination, wastewater from soil washing techniques, and leachate from contaminated soils. Soil techniques will address in situ as well as active land farming techniques. Whole cell and enzymatic approaches are being investigated. The nitrate esters used in this investigation are nitroglycerin (NG), propyleneglycol dinitrate (PGDN), trimethylolethane trinitrate (TMETN), and triethyleneglycol dinitrate (TEGDN). Working with the University of Maryland at Baltimore, we are isolating the enzymes used by bacteria to denitrify the nitrate esters. This technique can be used for both contaminated soils and wastewaters. For the whole cell approach we are working with the University of Cincinnati on the study of the kinetics for the biodegradation of nitrate esters in soil. Two organisms have been isolated that are capable of denitrifying nitrate esters; Bacillus thuringiensis/cerus (N) and Enterobactor agglomerans (AT25). We will present the results of C-14 NG and C-14 PGDN studies that show complete denitrification to glycerol and propylene glycol respectively by enzyme extracts from the Bacillus organism. The status of the work on isolating and identifying this enzyme will be reported. The results of kinetic study of the biodegradation of nitrate esters in soil performed at the University of Cincinnati will be presented. Author

The wastewater sludge generated by the manufacture of military pyrotechnics at Longhorn Army Ammunition Plant (LHAAP) is a listed hazardous waste (KO44) that also contains several toxicity characteristic leachate procedure (TCLP) metals - barium, chromium and lead - as well as various toxic organics. Currently, this hazardous waste is disposed of in a controlled landfill, which is expensive and leaves the government with a potential liability in case of a future accidental release to the environment. Plasma arc pyrolysis is an ultra-high temperature process that destroys all organics and renders TCLP metals non-leachable by sealing them into a fused vitreous slag, resulting in a non-hazardous material that can be placed in an uncontrolled landfill or used as a construction material. This paper evaluates the use of an improved small-scale plasma arc centrifugal treatment (PACT) unit with a secondary combustion chamber (SCC) and a high-efficiency off-gas treatment baghouse to treat the LHAAP sludge. To underscore the ability of plasma arc pyrolysis to render TCLP metals nonleachable, 1-2% each of barium, chromium and lead compounds were added to one batch of sludge. In addition, 2% hexachlorobenzene, a semi-volatile TCLP organic used in pyrotechnic manufacture, was added in order to perform a modified DRE (destruction and removal efficiency) test to confirm organics destruction. Partitioning of the volatile metals, lead and chromium, between the slag and the off-gas particulate were also investigated as part of process development. This test has demonstrated that plasma arc pyrolysis can be used for the destruction of listed military pyrotechnics manufacture wastewater treatment sludges containing TCLP metals and toxic organics. However, unexpected problems with the analyses and mass balances led to a number of 'lessons learned' that will be applied to a planned new test. Author

RECOVERY, EVALUATION, AND DECONTAMINATION OF LANDFILLED PENTABORANE CYLINDERS, FORMER LIQUID PROPELLANT ROCKET ENGINE TEST FACILITY, WASHOE COUNTY, NEVADA **c45**

S. L. Shestag, C. J. Rozas, R. Gnat (Hydro-Search, Denver, CO.), and J. Gold (Integrated Environmental Services, Atlanta, GA.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 81-91 (For primary document see N95-28294 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

During excavation of a landfill associated with a former liquid propellant test facility, forty eight pentaborane cylinders were discovered. The test facility was part of a 126,000 acre property used for liquid propellant rocket engine and solid propellant testing in the 1960's. Operations at the test facility ceased in 1970 and the area was later developed into a rural residential community. Because of the extreme toxicity of pentaborane and the proximity of the cylinders to adjacent residents, minimizing the potential for a release of pentaborane to the atmosphere was critical. Upon encountering the initial cylinder, preparation of a work plan for the safe handling, decontamination and disposal of cylinders was developed. Review of available information and knowledgeable sources indicated that no procedure for handling pentaborane cylinders of unknown integrity had been previously developed. Development of the work plan included air dispersion modeling to evaluate potential area of impact in the event of a release and evaluation of treatment and disposal options. Two onsite treatment methods were identified for decontaminating the cylinders. They included pyrolytic incineration if the cylinders contained pentaborane and chemical treatment for decontaminating the empty cylinders. Upon excavating and inspecting the cylinders, all were found to contain only residual quantities of pentaborane, if any. The chemical treatment process was used to decontaminate the cylinders. After controlled venting of any hydrogen gas which may have accumulated in the cylinders, residual pentaborane was dissolved with dilute caustic solution. Methanol was used to rinse the cylinders and then they were flushed with large quantities of water. The caustic rinse solution was neutralized in a reaction vessel using sulfuric acid. The process resulted in generation of non-hazardous waste products including boric acid, alcohol/water mixture and neutralized solid residue. Stored and landfilled pentaborane cylinders are known to exist at other similar installations. The procedures presented herein provide a reference

method for the safe handling and decontamination of potentially toxic pentaborane cylinders. The handling and treatment process developed resulted in the safe decontamination and disposal of the cylinders.

THREE-DIMENSIONAL FORECAST MODELS FOR EMERGENCY RESPONSE MANAGEMENT c45
Ted Yamada *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 93-100 (For primary document see N95-28294 09-20)
(Contract F08637-94-C-6013)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

An innovative scheme was developed to interactively operate HOTMAC, a three-dimensional mesoscale forecast model, and RAPTAD, a three-dimensional Lagrangian statistical diffusion model. HOTMAC runs continuously and always maintains a 24-hour forecast of meteorological data. The interactive scheme dictates that as soon as RAPTAD starts computation, HOTMAC halts its forecasting so that all computational power is used for RAPTAD. RAPTAD displays an hourly surface-concentration distribution plot on the screen as soon as one hourly computation is completed. The RAPTAD computation is fast compared with the HOTMAC computation, typically taking less than 20 sec. for a one hour simulation on a SPARC10 workstation. The HOTMAC/RAPTAD modeling system is operational on a desk-top or lap-top workstation. Thus, the HOTMAC/RAPTAD modeling system can be used for emergency response management to predict concentration distributions of toxic materials over complex terrain.

CHEMICAL REACTIONS IDENTIFIED IN THE TITAN 2, TITAN 4, AND DELTA 2 PROPELLANT SYSTEMS AND THEIR APPLICATION TO SOURCE MODELING
S. P. Prince, D. W. Banning, and F. L. Wiseman (Air Force Systems Command, Tyndall AFB, FL.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 101-112 (For primary document see N95-28294 09-20)
(Contract F08635-92-C-0056)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A series of tests involving the combustion of solid and liquid propellants used to fuel the Titan 2, Titan 4, and Delta 2 launch vehicles was performed. The purpose of these tests was to evaluate the nature and amounts of combustion gases from reacting these propellants in various proportions, and to apply the derived data to predicting toxic chemical emissions arising from a launch vehicle explosion. Propellants tested in this study included Aerozine-50 and nitrogen tetroxide (liquid propellants used in the Titan 2 and Titan 4 launch vehicles), PBAN solid propellant (used on the Titan 4 solid rocket motor), RP-1 and liquid oxygen (liquid propellants used to fuel the Delta 2 launch vehicle), and the Castor IVA solid rocket propellant used on the Delta 2 first stage engine. Tests were conducted in a 150-liter stainless steel combustion chamber in air at nominal pressure (0.8 atmospheres at Denver barometric conditions). Measurements of the chamber gas temperature and internal pressure were taken and gas samples were withdrawn and analyzed for expected combustion gases, unreacted propellants, organic vapors, and oxygen reacted from the air. A stainless steel witness plate was used to collect condensates which formed during the course of the propellant combustion tests. Results of this study suggest significantly different chemical fates for some of the rocket propellants than those predicted by chemical theory only. A description of the test parameters, results, and application to source predictions is presented.

USE OF SURFACE CHEMKIN TO MODEL MULTIPHASE ATMOSPHERIC CHEMISTRY: APPLICATION TO NITROGEN TETROXIDE SPILLS c45
Brian B. Brady and L. Robbin Martin *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 113-122 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

SURFACE CHEMKIN is a widely available computer program developed for kinetic modeling of chemical vapor deposition. We show that it may be adapted for kinetic modeling of multiphase chemistry in the atmosphere, with broad capability to deal with complex chemistry and physics. It can deal with multiple phases having different reaction manifolds in each phase, it deals with gas, surface, and bulk reactions and mass transfer rates, it keeps track of the phase equilibria with realistic activities, and it can operate in an adiabatic mode to include the effect of heat release on the system. The adapted model is applied here to the problem of a nitrogen tetroxide spill in the troposphere. The model is able to predict the formation of a nitric acid/water aerosol and to follow the chemistry taking place in both the gas and liquid phases as the spill dilutes in the surrounding atmosphere. The model predicts that in such a spill, most (70 - 90%) of the nitrogen oxides released are converted to nitric acid over a wide range of relative humidity.

UPGRADE OF THE COMPUTER MODELING PROGRAMS POLU10 AND POLU13A FOR OPEN BURNING AND OPEN DETONATION OF ENERGETIC MATERIALS c45
Edward E. Baroody *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 123-131 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Two popular ways to dispose of explosives and propellants (energetic materials) are by burning or detonating in the open air(OB/OD). Both methods have been used at disposal sites for many years as the safest, most cost effective means of treatment of reactive wastes associated with the production, use, maintenance an demilitarization of munitions and ordnance. To protect the environment, the disposal employing OB/OD sites are carefully controlled and must be issued an OB/OD permit by the State Environmental Protection Agency (EPA). This permit comes under the Resource Conservation and Recovery Act (RCRA) Part B permits, and the OB/OD sites are regulated by the EPA final hazardous waste management regulations under 40 CFR subpart X. A screening technique is required to provide a rapid and inexpensive approach to determine if the disposal site has the potential to cause adverse health impacts due to air emissions. This involves the use of computer models to estimate air emissions and the resultant ambient downwind concentrations of pollutants of concern. A computer program, POLU10, was developed to predict the pollution product caused by the OB/OD of energetic materials. The data from the POLU10 program have been used extensively by military sites to obtain OB/OD permits for the disposal of energetic materials. The program is referred to several times in the AEHA manual for application of OB/OD permits. As a result, copies of the POLU10 computer program have been sent to numerous military sites and their subcontractors. Author (revised)

CAPE CANAVERAL AIR STATION LAUNCH EMERGENCY RESPONSE FORCES AND TOXIC MATERIALS RELEASE CONTINGENCY PLANS c81
S. W. Brown *In* Johns Hopkins Univ., The 1994 JANNAF Safety and

Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 143-148 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Toxic materials release contingency plans and launch emergency response plans have been developed/revised for the Cape Canaveral Air Station (CCAS). This paper will describe the various emergency response plans utilized at CCAS to process and launch Expendable Launch Vehicles (ELV). The plans define the roles and responsibilities of the various disaster response elements, the chain of command for a given hazardous material release, post accident procedures for propellant spills, and catastrophic launch accident preparations. The Launch Emergency Response Force (LERF) plan and the Major Accident Response Exercises (MARE) performed at the CCAS are described. The use of real time toxic plume dispersion models during the implementation of the CCAS emergency response plans is also explained. Author

EVALUATION OF A CONDUCTIVE POLYMER-BASED SENSOR FOR DETECTION OF HYDRAZINES AT THE PART-PER-BILLION LEVEL **c25**
Dale Lueck, Dan Curran (I-NET, Inc., Cocoa Beach, FL.), and Mitch Zakin (Spectral Sciences, Inc., Burlington, MA.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 149-156 (For primary document see N95-28294 09-20)
(Contract NAS10-11943)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A conductive polymer-based hydrazine sensor (CPHS) was developed by Spectral Sciences, Inc., and Spire Corp. under an Small Business Innovative Research (SBIR) contract for the United States Air Force (USAF). During preliminary testing, the sensor showed promise as a dosimeter with the ability to detect hydrazine (N2H4) and unsymmetrical dimethylhydrazine (UDMH) at levels well below the proposed threshold limit value (TLV) of 10 part per billion (ppb). The original sensor developed and tested by Spectral Sciences and Spire Corp. demonstrated a minimum detectable dose of approximately 1 part per billion-hour (ppb-hr) and a saturation dose of approximately 250 ppb-hr in dry conditions, offering adequate coverage of the proposed TLV limit of 80 ppb-hr (8 hours at the proposed TLV level of 10 ppb). However, initial testing in a more realistic humidified environment (relative humidities (RH) to over 60%) indicated an increased sensor reactivity, yielding a saturation dose of only approximately 30 ppb-hr at humidities greater than 60%. A second version of the sensor (CPHS2) was fabricated utilizing a thicker polymer film in an attempt to increase the saturation dose back up to a level that would provide a better dynamic range. Initial tests of the CPHS2 by Spectral Sciences at the NASA Toxic Vapor Detection Laboratory (TVDL) in November 1993 exhibited a minimum detectable dose in the range of 1 to 2 ppb-hr, an increase in the saturation dose to approximately 150 ppb-hr in humid conditions and a measurement accuracy of +/-20%. The CPHS2 sensors are currently undergoing tests at the TVDL. The TVDL has the unique ability to generate calibrated sample vapor streams of N2H4 and UDMH over a range from less than 10 ppb to thousands of parts per million (ppm) with full environmental control of humidity (0 to 90%) and temperature (0 to 50 C). The polymer-based sensors will be subjected to extensive testing over a wide range of humidities at N2H4 and UDMH concentrations of 12.7 an 10.6 ppb respectively. Author

PROTOTYPE DEVELOPMENT AND TEST RESULTS OF A CONTINUOUS AMBIENT AIR MONITORING SYSTEM FOR HYDRAZINE AT THE 110 ppb LEVEL **c45**
Dale E. Lueck, Barry Meneghelli (I-NET, Inc., Cocoa Beach, FL.), Clyde Parrish (I-NET, Inc., Cocoa Beach, FL.), and Ron Barile (I-NET, Inc., Cocoa Beach, FL.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 157-166 (For primary document see N95-28294 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A Hydrazine Vapor Area Monitor (HVAM) system is currently being field tested as a detector for the presence of hydrazine in ambient air. The MDA/Polymetron Hydrazine Analyzer has been incorporated within the HVAM system as the core detector. This analyzer is a three-electrode liquid analyzer typically used in boiler feed water applications. The HVAM system incorporates a dual-phase sample collection/transport method which simultaneously pulls ambient air samples containing hydrazine and a very dilute sulfuric acid solution (0.0001 M) down a length of 1/4 inch outside diameter (OD) tubing from a remote site to the analyzer. The hydrazine-laden dilute acid stream is separated from the air and the pH is adjusted by addition of a dilute caustic solution to a pH greater than 10.2 prior to analysis. Both the dilute acid and caustic used by the HVAM are continuously generated during system operation on an 'as needed' basis by mixing a metered amount of concentrated acid/base with dilution water. All of the waste water generated by the analyzer is purified for reuse by Barnstead ion-exchange cartridges so that the entire system minimizes the generation of waste materials. The pumping of all liquid streams and mixing of the caustic solution and dilution water with the incoming sample are done by a single pump motor fitted with the appropriate mix of peristaltic pump heads. The signal to noise (S/N) ratio of the analyzer has been enhanced by adding a stirrer in the MDA liquid cell to provide mixing normally generated by the high liquid flow rate designed by the manufacturer. An onboard microprocessor continuously monitors liquid levels, sample vacuum, and liquid leak sensors, as well as handles communications and other system functions (such as shut down should system malfunctions or errors occur). The overall system response of the HVAM can be automatically checked at regular intervals by measuring the analyzer response to a metered amount of calibration standard injected into the dilute acid stream. THE SENSITIVE DETECTION OF HYDRAZINE USING CHEMILUMINESCENCE **c25**
G. E. Collins and S. L. Rose-Pehrsson *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 167-176 (For primary document see N95-28294 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A novel, chemiluminescent detector for hydrazine vapor, N2H4, is described, capable of monitoring subparts-per-billion levels of hydrazine in air. The catalytic oxidation of hydrazine by colloidal platinum forms an intermediate, oxidizing agent (e.g. OH or O2) which subsequently oxidizes luminol, generating a chemiluminescence signal that is proportional to the hydrazine concentration. The major components of the instrument itself are a photomultiplier tube (PMT), a short length of glass tubing coiled directly in front of the PMT surface, a vacuum pump for sampling the air, and a peristaltic pump for circulating the liquid reagent. The liquid reagent is comprised of a basic solution (pH = 13) of luminol and colloidal platinum which is continuously recycled in front of the PMT. The chemiluminescent reaction is initiated by pumping the hydrazine vapor down a short length of teflon tubing that is concurrently transporting the liquid reagent. The liquid is collected in a modified glass bubbler and quickly sent to the PMT for detection. Studies have included the effect of pH, luminol and platinum concentrations, and air and liquid flow rates on the analytical characteristics of this system. A linear dynamic range for hydrazine has been obtained from 10 to 2000 ppb in air, with a response that is fully reversible and achieves plateau response in less than 2 minutes. Investigations have included the incorporation of these chemiluminescent reagents within thin, polymeric films in order to further simplify the instrumentation requirements for a hydrazine detection system. A solid phase, chemiluminescent detector operates by placing the solid film directly in front of the PMT surface, and using a vacuum pump to draw the hydrazine vapor across the surface of the film. Polymers exhibiting different chemical character have been utilized as an additional parameter for defining the selectivity of these devices. Author

Hypergolic propellants are used in spacecraft such as Space Shuttle, Titan, and others launched at Kennedy Space Center (KSC) and Cape Canaveral Air Force Station (CCAFS). Fueling and deservicing spacecraft constitute the bulk of operations in which environmental emissions occur. Monomethylhydrazine (MMH), nitrogen tetroxide (N2O4), and hydrazine (N2H4) are the main propellants of concern Federal and State regulations require that KSC and CCAFS measure the amount of hypergols released to the environment. However, existing stack monitoring procedures are not applicable to hypergol operations that are intermittent and forced through the scrubber by inert gases, either nitrogen or helium. NASA and I-NET Space Services developed and validated a method to measure the emissions of toxic vapors under conditions where measurement of the total flow rate through a scrubber is difficult if not impossible to determine. This method is based on: (1) accurate measurements of the scrubber efficiency (EFF) for each type of operation; (2) an estimate of the number of operations and their contributions to the total annual flow through the scrubber; and (3) a measure of the concentration change of toxic vapors trapped by or reacted with reagents in the scrubber liquor. The concentration change of the component of interest in the scrubber liquor before and after an operation can be used to calculate the emissions. For example, the increase of hypergol in the scrubber solution was used to calculate the amount of hypergol that passed through the scrubber: Emissions (wt.) = ((1/EFF) - 1) x change in (wt. of hypergol). Emissions based on the scrubber liquor compared closely with emissions measured under controlled conditions where gas concentrations and total flow rate were known. A special sample system was constructed at the Toxic Vapor Detection Laboratory (TVDL) of KSC to measure hypergolic fuel or oxidizer in sample gas entering and exiting the test scrubber. The sample system was enclosed in a purged cart, except for tubing and valve electrical service leading to the sample ports and for sample valves positioned at the sample ports. This permitted operation of the sampling system during hazardous operations. This system and the data collected to validate the system are presented. Author

A CONTINUOUS EMISSIONS MONITOR FOR AIRBORNE METALS **c45**
Michael D. Seltzer *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 187-194 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Instrumentation, capable of continuous emissions monitoring of airborne metals, was recently tested in conjunction with the evaluation of an experimental incinerator used for the demilitarization of pyrotechnic materials. A sample air stream was continuously transported from the incinerator stack to a computer-controlled inductively coupled plasma spectrometer to allow real-time detection of entrained airborne metals by atomic emission spectrometry. Realtime detection of hazardous air pollutants offers several advantages over slower, more conventional techniques including the potential for active process control efforts aimed at ensuring environmental compliance. Details of instrument design, calibration, sample transport, and results of preliminary field testing are presented. Author

The sensitive detection and monitoring of trace atmospheric vapors of energetic materials presents an important technical challenge for the defense of our troops as well as for aviation security, forensics, and demilitarization safety applications. In this paper, we report a new method for detecting trace atmospheric vapors of NO2-containing compounds using one color laser photofragmentation/fragment ionization spectrometry. An ArF laser is employed to both photolytically fragment the target molecules and ionize the characteristic NO fragments. The production of NO is hypothesized to result from a combination of two NO2 unimolecular fragmentation pathways, one yielding NO in its (Chi(2)2) electronic ground state and the other in its Alpha(2)Sigma(+) excited state. Ionization of ground state NO molecules is accomplished by resonance-enhanced multiphoton ionization processes via their Alpha(2)Sigma(+) from Chi(2)2 (3,0), Beta(2)2 from Chi(2)2 (7,0) and/or Delta(2)Sigma(+) from Chi(2)2 (0,1) bands at 193 nm. The analytical utility of this method is demonstrated in a molecular beam time-of-flight apparatus. Limits of detection range from the parts-per-million (ppm) to parts-per-billion (ppb) level for NO, NO2, CH3NO2, dimethylnitramine (DMNA), ortho- and meta-nitrotoluene, nitrobenzene, and trinitrotoluene (TNT). Under effusive beam experimental conditions, discrimination between structural isomers, ortho-nitrotoluene and meta-nitrotoluene, has been demonstrated with the use of their characteristic photofragmentation/photoionization mass spectra. This technique is also useful for the detection and monitoring of environmental NO(x) pollutants for pollution prevention, compliance, and cleanup. Author

The Department of Defense has a technical requirement to develop alternative technologies to dispose of large numbers of solid propellant rocket motors while minimizing environmental impact. Research efforts conducted at the bench-scale have demonstrated the U.S. Army Missile Command (MICOM) near-critical fluid technology as a viable method of demilitarizing solid rocket motors. This method has been successfully used to recover valuable ingredients, such as cyclotetramethylene tetranitramine (HMX), cyclotrimethylene trinitramine (RDX), ammonium perchlorate (AP), and aluminum (Al)/binder crumb from tactical and strategic Class 1.1 and 1.3 solid propellants. This process utilizes liquid anhydrous ammonia for ingredient extraction and recovery. Under an Army-sponsored effort, Hercules Aerospace Company and Rust International have been awarded a contract to design and construct a pilot plant demilitarization test facility and to demonstrate this technology on Class 1.1 and 1.3 solid propellant tactical rocket motors. This report describes the hazards analysis efforts which have been ongoing since the start of the program. Hazards testing has characterized the sensitivity of propellants, process streams, and extracted materials. Hazards analysis techniques, such as logic diagrams, and failure modes and effects analysis (FMEA), have identified credible hazards in the equipment design and pilot plant operations. These potential hazards have been tracked by a closed loop system and have been mitigated by design features or operating controls. Major hazards identified will be discussed along with methods for mitigation. Also feedback from initial pilot plant operations will be reported to the extent that information is available. Author

This paper describes the development and implementation of a system safety program for the design, construction, test and validation of ground support systems for Atlas 2 rocket launching capability at Vandenberg Air Force Base. The SLC-3E project System Safety Program is based on MIL-STD-882B, specifically tailored for the upgrade. The program has tasks to cover the management and technical aspects of a System Safety Program. Management tasks include assurance of a good organization with qualified personnel and periodic reviews, and technical tasks include hazard analyses at both system and subsystem levels. One key aspect to the program was providing specific system safety training to system design engineers. As a result, with system safety engineers actively participating in product development teams, many safety issues were recognized by design engineers and resolved in the concept and preliminary design phases. In summary, this paper describes the management and technical tasks involved, several examples of building safety into design, examples of hazard mitigation by a disciplined analysis approach and risk acceptance process to assure safety consideration in all aspects of the project, and minimization of residual hazards in a complex construction project of this nature. A progress report is provided on a program developed to study through test and analysis, the characteristics of blast waves and fragmentation generated by ruptured gas filled pressure vessels. Prior papers on this USAF/NASA program have been presented to AIAA, to JANNAF, to the NASA Pressure Systems Seminar and to a DOD Explosives Safety Board subcommittee meeting. One Vessel has been burst with water pressure and eighteen with pneumatic pressure. All of the planned testing has been completed with the last test series having been completed in November 1993. The tests were designed to have a predetermined burst geometry and pressure level to study burst characteristics in an instrumented arena. Data trends for experiments are presented. The paper presents results from the last test series which were not available earlier and compares all the pneumatic burst test results. Author

ACUTE AND SUBACUTE TOXICITY OF AMMONIUM DINITRAMIDE (ADN) **c52**

D. R. Tocco, S. A. Salins (ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH.), R. E. Wolfe (ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH.), and E. R. Kinkead (ManTech Environmental Technology, Inc., Wright-Patterson AFB, OH.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 331-334 (For primary document see N95-28294 09-20)
(Contract F33615-90-C-0532)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Ammonium Dinitramide (ADN) is currently being considered to replace ammonium perchlorate by the Department of Defense. The chemical will be used in solid rocket engine propellant mixtures as well as a high explosive. No acute or chronic toxicity data is currently available for ADN, however field reports from exposed personnel indicate that the chemical is readily absorbed by the skin, resulting in numbness of the fingers. Because the most significant exposure route expected for ADN would be dermal exposure or possibly accidental ingestion, acute oral and dermal toxicity tests were conducted. In preparation for a reproductive screen on ADN, stability and palatability studies were also conducted. Oral administration of ADN at 5g/kg body weight (EPA limit dose) produced convulsions and rapid death in all treated rats. Subsequent studies indicated an acute LD(sub 50) in F-344 rats of 823 mg/kg. Dermal application of 2g/kg (EPA limit dose) produced no toxic signs in rabbits. Administration of either 12, 25, 50, or 100 mg ADN/ml drinking water on a continuous basis for 2 weeks to male and females SD rats produced no apparent effect on body weight gains, water consumption, organ weights, hemoglobin concentration, or methemoglobin formation. A reproductive toxicity screen of ADN in drinking water is currently in progress. Author

TOXICITY ASSESSMENT OF LIQUID PROPELLANT XM46 **c52**

Daniel J. Caldwell *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 335-342 (For primary document see N95-28294 09-20)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Liquid propellant XM46 is a developmental propellant that will be used with the regenerative injection gun in the Advanced Field Artillery System. The components of XM46 are both strongly reducing and oxidizing agents, are corrosive, and possess strong nitrating characteristics. XM46 is moderately toxic; the primary systemic effects are the production of methemoglobin, altered liver function, and enlargement of the spleen and liver. XM46 also produces skin irritation, is a strong eye irritant, and causes skin sensitization in guinea pigs but not humans. Aerosolized XM46 produces respiratory irritation. Genotoxicity evaluations of XM46 were negative. Since the Army recently opened to women many previously male-only occupational specialties, women now face potential accidental exposure to XM46 during both operational and maintenance procedures. XM46 was evaluated to determine its potential to produce reproductive toxicity, such as alterations in paternal fertility, maternal pregnancy and lactation, and growth and development of offspring. Sprague-Dawley rats were dosed with 200, 1000, or 2000 mg XM46 per liter of drinking water (target dose of 12, 60, and 120 mg of XM46 per kg body weight per day, i.e., mg/kg/day) for 14 days prior to mating, during gestation, postpartum (21 days), and for four weeks postweaning for a total of 90 days. Pups were maintained on treated water for four weeks postweaning. Although there were dose related effects in parental animals, there were no treatment related adverse reproductive effects (mating, fertility index, length of gestation, sex ratio, gestation index, or mean number of offspring per litter) compared to control (i.e., non-treated) animals. Mean pup weights showed no statistically significant differences between treated and control groups. In a mouse dominant lethal assay, XM46 was shown not to have dominant lethal effects on fertility or reproduction at doses of 100, 200, and 400 mg/kg/day compared to control animals. A teratology study was undertaken to determine if XM46 causes birth defects in the developing fetus. Animals were treated with XM46 at doses of 162.5, 325, and 650 mg/kg/day during the major period of organogenesis to determine if developmental variations and malformations were produced in offspring. The incidence of fetal death (number of dead fetuses plus the number of resorptions) was not significantly different between dose groups. The number of live fetuses per litter was not significantly different between dose groups. No evidence of fetal toxicity related to XM46 exposure was noted in any of the dose groups. Based on these data it is concluded that XM46 is not a reproductive toxicant or teratogen in the rat. Author

The reformulation of military explosives and solid propellants into commercial explosives offers a unique solution to the problem of disposing of high energy materials with essentially zero environmental impact at a low cost and with a salable product. Studies using the insensitive PBX, PBXN-4 have been completed through the pilot plant stage and have been successfully tested as a mining explosive. A number of other military explosives have been examined and their VOD's (velocity on detonation) and heats of explosions determined and in some instances tested in 'field' operations. The equipment and unit operations required for reformulation are simple and inexpensive. The total market potential is far larger than the available supply of PBX's and other military explosives. The extension of the reformulation approach to 1.1 solid rocket propellants is in progress. Initial studies indicate that the method is viable. The quantities involved have the potential of impacting less than 1% of the very large US explosives market. The products available from reformulation are in part a function of the means of removal of the 1.1 propellants from the cases. With dry methods, a range of products from 'super' blasting gelatins to materials comparable to ANFO are available in the form of dry or slurried explosives. With wet methods, the range is narrower with VOD's of approximately 4 km/sec and heats of explosion of approximately 1000 cal/g at a density of 1.25 g/cc being easily attainable in the form of slurries. With both HE and 1.1 propellant streams it is possible to tailor the power of the resultant explosives to reach a desired set of properties. This permits the handling of a variable stream of redundant materials and the furnishing of a 'constant' product to the customer. The technology involved has essentially no waste stream and very closely meets the goals of the US Resource Conservation and Recovery Act (RCRA). Author

The research presented herein is the result of efforts under subcontract to United Technologies Chemical Systems Division San Jose, California. The efforts were focused on investigating the feasibility of using excess rocket propellants from both production processes and demilitarization processes as ingredients in commercial explosives. Both Class 1.3 and Class 1.1 propellants were evaluated. As a result of the tests presented herein, a Propellant Evaluation Model (PEM) was developed which will provide guidelines for future work in the same area. According to the United States Department of the Interior, Bureau of Mines, the United States uses over 2 million metric tons (4 billion pounds) of commercial explosives per year. Of this quantity, approximately 600 million pounds are used which would provide the most feasible avenue for the inclusion/incorporation of solid rocket propellants. The possibility of using these rocket propellants in even a small portion of the commercial explosives which are used presents a significant outlet. This paper discusses the findings of research in which several Large Rocket Motor Propellants were evaluated for use as ingredients in commercial explosive formulations. Aspects such as chemical compatibility, processing safety, and final product performance were investigated. Explosive characteristics such as detonation velocity, critical diameter, and energy release were also measured. It was concluded that the use of each of the propellants which were evaluated would be beneficial in several areas. The propellant/commercial explosive blended products exhibited significantly enhanced explosive characteristics over those of the standard formulations. The alternate use of the propellants would give them a 'useful product' status and remove them from a 'hazardous material' status. Finally, this alternate use could be accomplished in an economical method which would allow for significant cost avoidance over less desirable methods of disposal of these materials. The alternate use approach discussed should not be seen as a disposal technology. It is a resource recycling approach which can be done economically, safely, and in an environmentally sound manner. THE DEMILITARIZATION OF CLASS 1.1 ROCKET MOTORS USING HIGH PRESSURE WATERJETS c28

Oliver Sitton, Paul N. Worsey, David Summers, Karla Bier, Dan Burch (Naval Surface Warfare Center, Crane, IN.), and Mike Johnson (Naval Surface Warfare Center, Crane, IN.) *In* Johns Hopkins Univ., The 1994 JANNAF Safety and Environmental Protection Subcommittee Meeting, Volume 1 Aug. 1994 p 371-379 (For primary document see N95-28294 09-20)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The Naval Surface Warfare Center, Crane Division (NAVSURFWARCENDIV) has been tasked by the Joint Service Large Rocket Motor Disposal Program to develop high pressure waterjet technology to remove Class 1.1 propellant from large rocket motors. A contract was awarded to the Rock Mechanics and Explosives Research Center (RMERC) at the University of Missouri-Rolla (UMR) to validate the safety of the washout operation and demonstrate the capability to effectively washout the propellant and treat the process streams. The ultimate goal of the project is to recover the propellant for use as commercial blasting agents. RMERC, in support of the Navy, had demonstrated in the past the applicability of using high pressure waterjets to demilitarize PBX warheads. The washout of Class 1.1 propellants containing nitroglycerine (NG) and ammonium perchlorate (AP) has raised safety concerns regarding the sensitivity of the propellant to washout impact pressures and the treatment of the process streams. A systematic approach was developed by NAVSURFWARCENDIV Crane and RMERC to demonstrate the viability of the high pressure waterjet technology: the determination of waterjet impact sensitivity, cutting parameterization, process streams characterization, NG safety assessment, subscale motor washout and process streams treatment. Testing conducted to date on samples of five different Class 1.1 propellants from Navy, Air Force and Army missiles showed that all of the propellants can be effectively removed at a waterjet pressure of 69 MPa (10,000 psi) with a minimum safety factor of 16. The analysis of liquid samples from parameterization show that the water is not saturated in NG for each of the propellants. AP, Resorcinol and NG showed the highest solubilization into the water phase. Work is on-going in assessing potential technologies for the treatment of the NG/AP containing streams. RMERC is currently washing out subscale motors utilizing their Waterjet Ordnance and Munition Blastcleaner with Automated Tellurometry (WOMBAT) which is located in an underground facility and remotely operated by computer control. TPL is conducting a comprehensive program in energetic materials resource recovery and recycling (R3), developing environmentally acceptable reprocessing methods, and formulating the recycled materials into high valued commercial products. Energetic materials investigated include: plastic-bonded and conventional explosives, nitrocellulose (NC)-based propellants, Hazard Class 1.1 an 1.3 propellants, pyrotechnics, and primers. The majority of this work has been conducted as part of the Ordnance Reclamation Program of the Naval Sea Systems Command. Implementation of aspects of the developed technologies into operational status has been achieved through participation in the AMCCOM Conventional Ammunition (Small Arms) Resource Recovery Program and technology development support has also been provided through the U.S. Army's Demilitarization R&D Program as well as IRAD funds. TPL's experiences in the R3 of three classes of energetic materials are summarized. Author (revised)

Cryogenic washout (U.S. Patent No. 5025632) is a process using liquid nitrogen (LN2) as a washout medium to remove the propellant from within solid rocket motors. The process produces dry, size reduced particles which are well suited for disposal or for reuse in applications such as commercial explosives. A prototype cryogenic washout facility is being readied for testing on Minuteman II Stage III motors, under contract to the U.S. Air Force. Design support testing for the facility has been completed, and an overview of test results is presented. Design support testing included laboratory and bench-scale testing on Hazard Class 1.1 and 1.3 propellants. The laboratory tests established that essentially no change in the sensitivity of the test propellants occurred between ambient and cryogenic temperatures. Recent bench scale testing utilized LN2 pressures of up to 117 MPa (17,000 psi) and flow rates up to 6.4 X 10(exp -4) cu m/s (12 gpm) to demonstrate cryogenic washout rates of up to 0.1 kg/s (765 lb/hr) for Class 1.1 propellant. This represents a 'removal efficiency' of 0.17 kg propellant per kg LN2. Further improvements in propellant removal rate and efficiency are expected during prototype testing in 1994. The prototype equipment design is described with emphasis on engineered safeguards. Challenging operating environments include cryogenic temperatures and high pressures. Author

Hydrothermal oxidation (HTO), also referred to as supercritical water oxidation, is an emerging technology for the destruction of hazardous and nonhazardous wastes. HTO destroys combustible materials using an oxidation in water process at temperatures in the range of 350 C (662 F) to 600 C (1112 F) and pressures of 17 MPa (2500 psi) or greater. Relative to incineration, HTO offers the advantages of lower temperature oxidation, compact reactor design, enhanced process stability, low NO(x) and SO(x) production, and complete containment of all effluents. Oxidation is accomplished under near-homogenous, single-phase conditions which provide excellent mixing and high mass and heat transfer rates. High destruction efficiencies are achieved in relatively small reactor volumes. Oxidation is performed in a completely enclosed system, permitting full containment of all process effluents prior to subsequent analysis and release. Relative to other non-incineration technologies (e.g., wet air oxidation), HTO offers the advantage of conversion of hazardous waste to environmentally benign products in a single process without the need for follow-on treatment or processing. The results of two ongoing research and demonstration programs conducted by General Atomics (GA) and its subcontractors for the application of HTO to DOD waste problems are updated. Both programs call for design, construction, and testing of prototype plants with throughputs of 0.026 l/s to 0.066 l/s (600 to 1500 gal/day). The first program, performed for the U.S. Air Force involves the treatment of a Hazard Class 1.1 solid propellant removed from rocket motor casings. The second program, performed for the Advanced Research Projects Agency (ARPA), involves the treatment of solid propellants as well as chemical agents and other DOD wastes. Author

The Department of Defense (DOD) has a technical requirement to develop alternative, rocket motor demilitarization technologies which are environmentally safe and affordable. Environmental regulations now require industry and government agencies to conserve resources, when technically feasible, through the reclamation and reuse of commodities that otherwise would be incinerated or destroyed. The technical capability to recover and reclaim valuable ingredients and hardware components from both class 1.1 and 1.3 solid rocket motors has been demonstrated. This Army developed technology is being scaled for demonstration in an integrated, rocket motor demilitarization pilot plant that is nearing construction completion. Reclaimed RDX is being evaluated for potential commercial and military reuse. The U.S. Army TOW-2 flight motor was used for demonstrating the recovery of RDX for reuse/recycle in a commercial mining cast booster. Standard one pound cast boosters were manufactured by Austin Powder Company using the reclaimed RDX and compared to a standard 'Orange Cap' Composition-B, commercial mining booster. Booster tests were conducted by Austin Powder Company and the U.S. Bureau of Mines. Detonation velocity, borehole field validation, and hazards characterization testing were performed. Test results confirm that the reclaimed/recycled RDX cast booster was virtually identical to the commercial product. Author

One of the objectives of the LDEF Special Investigation Group (SIG) was to develop a LDEF data base that identifies the experiment objectives and hardware flown, summarizes results and conclusions, and provides a system analysis overview, including spacecraft design guidelines and space environmental effects. Compiling the information into an easily accessible data base format, and making it available to the space community was a major task accomplished by the System and Materials SIG effort beginning in 1891. Included in this document is a short user's manual for the LDEF Mini-Data Bases. The user's manual contains pertinent examples from the data base on specifically how to access and work with the LDEF information. Accompanying this document are the mini-data bases on disk. Author

EXTENDED EQUATION-OF-STATE FOR DICHLORODIFLUOROMETHANE (CCl2F2) Technical Report, 10 Feb. 1992 - 21 May 1993
Alan I. Lampson, Peter G. Crowell, and Gary P. Ganong 1 Dec. 1994 66 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DNA001-93-C-0138)
(AD-A288885; DNA-TR-94-25) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A new equation-of-state for decomposed CCl2F2 (dichlorodifluoromethane) has been developed. This new equation-of-state is based upon equilibrium composition calculations of the components and possible products of CCl2F2 and utilizes tables of thermochemical properties for each of the gas species. Since the thermochemical property tables had an upper temperature limit of 6000 K, these tables first had to be extended to cover the temperature range of interest. The new equation-of-state covers the pressure range of 0.1 to 100,000 bar and the temperature range from 200 to 30,000 K, and with certain limitations, up to 500,000 K. The methods used to extend the thermochemical tables and to determine the equilibrium gas composition are described. DTIC

NMR spectroscopy identified the main impurity in DAST films grown by OVPD method. The impurity is a trimethilated compound described previously. Thus our films consist of over 90% DAST and some 5 to 10% of the above impurity. An apparatus for measuring second harmonic generation properties of OVPD DAST films has been constructed and described. The optimization of growth conditions of the OVPD method is described. DTIC

We report electrochemical and in situ atomic force microscopy observations of the formation of a new class of crystalline organic monolayer, which consists of a conductive organic salt containing bis(ethylenedithiolo)-tetrathiafulvalene (ET), on highly oriented pyrolytic graphite (HOPG). Growth of this monolayer accompanies the electrochemical oxidation of ET in the presence of the I3 (iodine 3) anion at a freshly cleaved HOPG electrode. The monolayer covers large areas of the graphite substrate (greater than 100 square micrometers) and can be removed at potentials cathodic of the ET/ET+ couple. High resolution AFM imaging of the monolayer and a 15.5 angstrom monolayer thickness are consistent with the formation of a single (001) layer of beta-(ET)2I3, with the long axes of the ET molecules oriented nearly perpendicular to the graphite basal plane. The preferential formation of beta(ET)2I3 over other polymorphs is a consequence of favorable epitaxial interactions between the overlayer lattice and that of the graphite substrate, and is manifest in selective growth of bulk beta(ET)2I3 crystals on this electrode surface. These results demonstrate that controlled deposition of conducting mono- and multi-layer films can be achieved in the presence of strong interfacial interactions during nucleation, suggesting a route to the fabrication of electronic devices based upon molecular design principles. The nonlinear optics of sublimated films of 2-dimensional conjugated planar molecules has been investigated by third harmonic generation. Two were planar phthalocyanines, metal-free and copper substituted, and the third was an asymmetric (non-planar) phthalocyanine (subphthalocyanine), employed as a precursor in the synthesis of certain phtalocyanines. A very rich spectrum has been observed in each case and the analysis is currently underway. In the future this work will be expanded to include other materials. DTIC

Finite difference for continuum mechanics codes are capable of providing solutions for the behavior of a wide range of materials under a variety of boundary and initial conditions. The key to obtaining accurate solutions lies in the fidelity of models used to describe the material's response to the strains imposed, i.e., its Equation of State (EOS). This report presents both the general EOS algorithms used in the CRALE 1- and 2D codes and several specific EOS models currently in use. A driver routine that exercises these models over specific load/unload paths is available to assist in developing and checking the parameters needed for materials of interest. A discussion of this driver and a users manual to assist in its use are also presented. In the course of developing EOS models of interest to DNA and as part of the TRT participation in the DNA HYDROPLUS program, a number of data bases have been developed. These include files containing; experimental shock Hugoniots and release paths, parameters for EOS models used in the HYDROPLUS program, and the nuclear shot experimental and calculational data bases developed for HYDROPLUS. A description of the various data bases with instructions for their access is included in this report. DTIC

COMPUTATIONAL AND MATRIX ISOLATION STUDIES OF (2- AND 3-FURYL)METHYLENE M.S. Thesis
Vincent A. McDermott 1994 126 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A280085) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

(2- and 3-Furyl)methylene were investigated using both ab initio molecular orbital calculations and matrix isolation spectroscopy. Initial approaches to 2-furylmethylene were via the diazirine precursor. However, its synthesis was never realized. We therefore formed the diazo precursor for both compounds and purified them in preparation for matrix isolation. Ab initio calculations on 2-furylmethylene predict that the o = 0 deg conformer 2.2 to be more stable than the o = 180 deg conformer 2.1 in both the singlet and triplet states. Additionally, the energy barrier for ring fragmentation of the singlet carbene is predicted to be - 2.5 Kcal/mol. For 3-furylmethylene, two different levels of theory predict the opposite ground state multiplicity. DTIC

SELF-ASSEMBLY OF LOW-DIMENSIONAL MOLECULAR NANOCLUSTERS ON Au(111) SURFACES Technical Report
Joachim Hossick Schott, Christopher M. Yip, and Michael D. Ward 8 Dec. 1994 34 p Revised Submitted for publication Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-0563)
(AD-A288936; TR-7-Rev) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Two-dimensional nanoclusters of (TTF)(TCNQ) (TTF = tetrathiafulvalene, TCNQ = tetracyanoquinodimethane) and Li(+)TCNQ(-), formed on Au(111) surfaces by vapor phase sublimation under ambient conditions prior to growth of bulk crystals of these low-dimensional organic conductors, have been observed with scanning tunneling microscopy (STM) and scanning electron microscopy (SEM). The molecular planes of the constituents in individual nanoclusters are oriented perpendicular to the Au(111) substrate, while the clusters exhibit azimuthal orientations conforming to the threefold Au(110) directions. The nanocluster morphology and structure suggest that self-assembly of the nanoclusters is governed by specific interactions between the molecular species and the substrate and molecular diffusion along (110) troughs on the Au(111) substrate surface. In the case of the (TTF)(TCNQ) nanoclusters, TTF and TCNQ molecules assemble into molecular rows normal to the stacking direction, with intermolecular distances along the stacking direction which are nearly identical to those observed in bulk (TTF)(TCNQ). In contrast, the intermolecular spacings between TCNQ molecules along the molecular stacking axis in Li + TCNQ nanoclusters are substantially larger than that observed in bulk M+TCNQ.salts. The large intermolecular spacing in Li + TCNQ.nanoclusters is consistent with Coulomb repulsion between fully reduced p = 1 TCNQ(dot) anion sites in the Li+TCNQ.nanoclusters (p = formal charge). Novel poly(N-arylenebenzimidazole)s (PNABIs) are prepared by the aromatic nucleophilic displacement reaction of novel di(hydroxyphenyl-N-arylene benzimidazole) monomers with activated aromatic dihalides or activated aromatic dinitro compounds. The polymerizations are carried out in polar aprotic solvents such as N-methyl-2-pyrrolidinone or N,N-dimethylacetamide using alkali metal bases such as potassium carbonate at elevated temperatures under nitrogen. The di(hydroxyphenyl N-arylenebenzimidazole) monomers are synthesized by reacting phenyl 4-hydroxybenzoate with bis(2-aminoanilino) arylenes in diphenylsulfone. Moderate molecular weight PNABIs of new chemical structures were prepared that exhibit a favorable combination of physical and mechanical properties. The use of the novel di(hydroxyphenyl N-arylenebenzimidazole)s permits a more economical and easier way to prepare PNABIs than previous routes. A STUDY OF THE USE BETA-ALUMINA AS A WEAK INTERFACE IN ALUMINA FIBER COMPOSITES Final Report, 1 Sep. 1991 - 31 Aug. 1994

Peter E. Morgan and David B. Marshall Nov. 1994 95 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-C-0157)
(AD-A288629; SC71056.FR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Results are presented from a three-year study aimed at identifying and developing suitable inter-phase materials for oxide-oxide composites that are stable in high temperature oxidizing environments, yet sufficiently weak to allow debonding as required for toughening. Most of the effort was devoted to two systems: LaPO4 (monazite) and beta-aluminas. Monazite satisfied all of the requirements for an interphase in alumina-alumina composites (and most likely many other ceramic matrix-fiber combinations). It has a high melting point (2074 C); it is stable with alumina at high temperature in both oxidizing and slightly reducing environments and it forms a sufficiently weak bond with alumina. Beta-alumina materials, which possess weak mica-like planes in their crystal structures, are phase compatible with alumina, and their debonding characteristics are adequate. However, their use and fabrication temperatures are limited by morphological instability of the fiber/matrix interface (grain growth of the beta-alumina platelets into the fibers). DTIC

A FAST NUMERICAL METHOD FOR ISOTHERMAL RESIN TRANSFER MOLD FILLING Final Report, Dec. 1993 - Apr. 1994

R. S. Maier, T. F. Rohaly, S. G. Advani, and K. D. Fickie Nov. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-62618-AH-80)
(AD-A288944; ARL-TR-610) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An efficient numerical scheme is presented for simulating the isothermal flow in resin transfer molding (RTM). The problem involves transient, free surface flow of an incompressible fluid into a nondeforming porous medium. A new variant of the control volume finite element (CVFE) algorithm is explained in detail. It is shown how the pressure solutions at each time step can be obtained by adding a single row and column to the Cholesky factorization of the stiffness matrix derived from a finite-element formulation for the pressure field. This approach reduces the computation of a new pressure solution at each time step to essentially just two sparse matrix back-substitutions. The resulting performance improvement facilitates interactive simulation and the solution of inverse problems which require many simulations of the filling problem. The computational complexity of the calculation is bounded by O(n sup 2.5), where n is the number of nodes in the finite element mesh. A 100-fold speedup over a conventional CVFE implementation was obtained for a 2213-node problem. DTIC

LIFE PREDICTION METHODOLOGY FOR COMPOSITE LAMINATES. PART 1: CONSTANT AMPLITUDE AND TWO-STRESS LEVEL FATIGUE Interim Report, 15 Jan. 1993 - 30 Aug. 1994
Jeffery R. Schaff and Barry D. Davidson (Syracuse Univ., NY.) Sep. 1994 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2419)
(AD-A288343; WL-TR-94-4046) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A strength-based wearout model is presented for predicting the residual strength and life of composite laminates subjected to constant amplitude or two-stress level fatigue loadings. It is assumed that the laminate undergoes proportional loading, that its residual strength is a monotonically decreasing function of the number of loading cycles, and that the probability of failure after an arbitrary number of cycles may be represented by a two parameter Weibull function. The model also incorporates a 'cycle mix factor' to account for the degradation of strength and life that may be associated with frequent changes in the stress amplitude of the loading. Experimental results from two-stress level loadings are used to evaluate the model's predictive capability for sequencing effects, as in a low-high or high-low test, and for cycle mix effects, as in a low-high-low-high repeating test. Good correlation between theory and experiment is obtained for all loadings and laminates studied. DTIC

INTERFACIAL MOBILITY AND ITS EFFECT ON FLEXURAL STRENGTH AND FRACTURE TOUGHNESS IN GLASS-FIBER FABRIC REINFORCED EPOXY LAMINATES Technical Report, 1 Jan. - 19 Nov. 1994
Timothy W. Wang and Frank D. Blum 21 Nov. 1994 8 p Sponsored by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288344; UMR-FDB-44) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Constant-strain-rate mechanical testing was used, to study the fracture mechanical characterization of E-glass fiber fabric reinforced epoxy composites. Testing was performed as a function of the silane coupling agent used with compact tension (CT) specimens for fracture toughness and rectangular specimens for flexural strength. Two silane coupling agents, y-aminopropyltriethoxysilane (APS) and y-aminobutyltrithoxy-silane (ABS) were used for this purpose. The fracture toughness, K1c, of ABS treated composites was shown to be lower than that for APS treated composites. Treatment with either is better than using bare glass. A three point bend test showed the flexural strength and modulus were increased in order of untreated<ABS<APS treated composites in both dry and wet conditions. Since these silanes have similar chemistry, we believe that the difference is due to the interfacial mobility of the coupling agent layer. DTIC

MICROMECHANICAL PREDICTION OF TENSILE DAMAGE FOR CERAMIC MATRIX COMPOSITES UNDER HIGH TEMPERATURE Final Report, 15 Aug. 1990 - 15 Feb. 1994
F. Delale and B. M. Liaw 15 Feb. 1994 142 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0341-90)
(AD-A288238; AFOSR-94-0701TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report documents the experimental and theoretical results obtained in studying the tensile damage behavior of ceramic matrix composites (namely Nicalon/CAS II composites) at room and elevated temperature. First the composite specimens were machined into dog-bone shape and polished to increase efficacy of observation in the SEM. Then the specimens were placed inside the chamber of a scanning electron microscope (SEM) and subject to tensile loading at room and higher temperatures up to 700 C. At each temperature, the load was increased until failure of the specimen and the progression of damage was observed and recorded from first crack to total failure. Damage usually started with matrix cracking, followed by debonding along fiber-matrix interface, fiber pullout and finally fiber breakage. At each load level, the displacement was measured, resulting in a stress-strain curve with linear and non-linear portions.Similar behavior was observed at higher temperatures. Theoretical models to predict and simulate the observed behavior were also developed. A singular integral formulation with periodic matrix cracking and interface debonding explains well the fact that embedded matrix cracks almost always propagate to the interface and are arrested by the fibers. The results obtained from finite element model with multiple rows of matrix cracks and debonding at the fiber/matrix interface, compare extremely well with the experimental data. DTIC

STATISTICAL ANALYSIS OF TENSILE MECHANICAL PROPERTY DATA OF CARBON/POLYIMIDE COMPOSITES
Toshiyuki Shimokawa, Yasumasa Hamaguchi, Yoshiaki Kakuta, Shigeo Sanbongi, Yoshiki Morino (National Space Development Agency, Tokyo, Japan.), and Masataka Yamamoto (National Space Development Agency, Tokyo, Japan.) Jun. 1994 17 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1238) Avail: CASI HC A03/MF A01

The objective of this study is to statistically evaluate the tensile mechanical properties of two kinds of carbon/polyimide composites, i.e., Celion 6K/PMR-15 and T800H/PMR-15 with a quasi-isotropic stacking sequence. Tensile tests were conducted under room temperature using about thirty smooth specimens. Mechanical properties measured are ultimate strength, failure strain, elastic modulus, and Poisson's ratio. Statistical analyses use four kinds of distribution models such as the normal, log-normal, type-1 extreme-value, and two-parameter Weibull distributions. These analyses derive the estimates of central tendencies and scatter parameters, and B allowables. The modified Kolmogorov-Smirnov goodness-of-fit of each mechanical property data for the four kinds of distribution models. Correlation between mutual mechanical properties is examined, and a multiple regression analysis is applied to predict the ultimate strength. Moreover, a simple equation to predict the ultimate strength is derived using the product of the failure strain and elastic modulus. Author

MICROENGINEERED CONDUCTING COMPOSITES FROM NANOCHANNEL TEMPLATES Technical Report
Carmen A. Huber, Mostafa Sadoqi, Tito E. Huber, and Daborah Chacko Jan. 1995 15 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289573; CARDIVNSWC-TR-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Metallic nanostructures can be prepared from nanochannel dielectric hosts by injection of the conducting melt. Nanowire arrays and random networks have been fabricated in this way. The role of the microstructure in the bulk electronic properties of the composites as well as applications of these materials are discussed. DTIC

COMPOSITE SANDWICH STRUCTURE AND METHOD FOR MAKING SAME Patent Application
Charles J. Magurany, inventor (to NASA) (Lockheed Engineering and Sciences Co., Hampton, VA.) 30 Mar. 1995 32 p
(NASA-Case-LAR-14898-1; NAS 1.71:LAR-14898-1; US-Patent-Appl-SN-413301) Avail: CASI HC A03/MF A01

A core for a sandwich structure which has multi-ply laminate ribs separated by voids is made as an integral unit in one single curing step. Tooling blocks corresponding to the voids are first wrapped by strips of prepreg layup equal to one half of each rib laminate so a continuous wall of prepreg material is formed around the tooling blocks. The wrapped tooling blocks are next pressed together laterally, like tiles, so adjoining walls from two tooling blocks are joined. The assembly is then cured by conventional methods, and afterwards the tooling blocks are removed so voids are formed. The ribs can be provided with integral tabs forming bonding areas for face sheets, and face sheets may be co-cured with the core ribs. The new core design is suitable for discrete ribcores used in space telescopes and reflector panels, where quasiisotropic properties and zero coefficient of thermal expansion are required. NASA

DUCTILE - DUCTILE BERYLLIUM ALUMINUM METAL MATRIX COMPOSITE MANUFACTURED BY EXTRUSION Interim Report, 1 Dec. 1994 - 1 Jan. 1995

Nancy F. Levoy 1 Jan. 1995 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-C-0135)
(AD-A289519) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The current program is designed to develop a method for extruding a cast beryllium-aluminum composite, establish a basis for estimating the properties that can ultimately be achieved with an optimized process, and produce an extruded structural shape of moderate complexity. Specific technical objectives are as follows: (1) Develop an extrusion process suitable for beryllium-aluminum composites that maximizes product yield, minimizes processing steps, gives good surface finish, and is suited for producing complex shapes; (2) Determine mechanical and physical properties to demonstrate potential; and (3) Define potential for property enhancements and cost reductions that could be achieved through continued development of this technology. FATIGUE BEHAVIOR OF A CROSS-PLY METAL MATRIX COMPOSITE AT ELEVATED TEMPERATURE UNDER STRAIN CONTROLLED MODE M.S. Thesis

Leon B. Dennis Dec. 1994 127 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289425; AFIT/GAE/ENY/94D-7) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research extends the existing knowledge of cross-ply metal matrix composites (MMC) to include fatigue behavior under strain-controlled fully reversed loading. This study investigated fatigue life, failure modes and damage mechanisms of the SCS-6/Ti-15-3, (0/90)2's, MMC. The laminate was subjected to fully reversed fatigue at elevated temperature (427 C) at various strain levels. Stress, strain and modulus data were analyzed to characterize the macro-mechanical behavior of the composite. Microscopy and fractography were accomplished to identify and characterize the damage mechanisms at the microscopic level. Failure modes varied according to the maximum applied strain level showing either mixed mode (i.e. combination of both fiber and matrix dominated modes) or matrix dominated fatigue failures. As expected, higher strain loadings resulted in more ductility of the matrix at failure, evidenced by fracture surface features. For testing of the same composite laminate, the fatigue life under strain controlled mode slightly increased, compared to its load-controlled mode counterpart, using the effective strain range comparison basis. However, the respective fatigue life curves converged in the high cycle region, suggesting that the matrix dominated failure mode produces equivalent predicted fatigue lives for both control modes. DTIC

VISCOPLASTIC CHARACTERIZATION AND FATIGUE MODELING OF TITANIUM BASED METAL MATRIX COMPOSITES M.S. Thesis

Mark A. Foringer Dec. 1994 105 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289430; AFIT/GAE/ENY/94D-5) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Viscoplastic characterization and fatigue modeling of titanium-based metal matrix composites was accomplished by combining a unified viscoplastic theory, a nonlinear micromechanics model, and a linear damage accumulation model. Ti 15-3 was characterized using the Bodner-Partom viscoplastic theory. A micromechanics model was then employed in a linear damage accumulation fatigue model to predict the fatigue behavior of titanium based composites. The viscoplastic behavior predictions of the micromechanics model were used to eliminate separately defined time dependent terms in the fatigue model. Also, a new linear damage accumulation model was developed from the fatigue behavior of the composite constituents. Finally, it was found that the microstresses in the 0 degree ply could be used to accurately predict the fatigue behavior of a laminate containing these plies. DTIC

CHARACTERIZATION OF FATIGUE BEHAVIOR OF 2-D WOVEN FABRIC REINFORCED CERAMIC MATRIX COMPOSITE AT ELEVATED TEMPERATURE Final Report M.S. Thesis

Daniel J. Groner Dec. 1994 128 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289423; AFIT/GAE/ENY/94D-15) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study investigated the fatigue behavior and associated damage mechanisms in notched and unnotched enhanced SiC/SiC ceramic matrix composite specimens at 1100 C. Stiffness degradation, strain variation, and hysteresis were evaluated to characterize material behavior. Microscopic examination was performed to characterize damage mechanisms. During high cycle/low stress fatigue tests, far less fiber/matrix interface debond was evident than in low cycle/high stress fatigue tests. Notched specimens exhibited minimal stress concentration during monotonic tensile testing and minimal notch sensitivity during fatigue testing. Damage mechanisms were also similar to unnotched. DTIC

EVALUATION OF COMPOSITE JOINTS Interim Report, Nov. 1993 - Apr. 1994

Seng C. Tan Apr. 1994 34 p Prepared in cooperation with Wright Materials Research Co. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-89-C-5643)
(AD-A289247; WL-TR-94-4077) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A study of bolted, bonded, and bolted-bonded composite single lap joints was conducted. Graphite thermoplastic composite material (AS4/APC2) and two stacking sequences, (0,90,45 ,135)2s and (0,0,45,135)2s, were used. Five joint designs were tested: (1) bonded (FM400); (2) bolted-bonded with two bolts; (3) bolted bonded with four bolts; (4) bolted with six bolts; and (5) bolted with eight bolts. Load deflection measurements were made and joint efficiencies computed. Failure mechanisms were determined. Peak joint efficiencies were in the 55% vicinity and occurred for the six-bolt configuration and the (0,90,45,135)2s laminate. For the tests in this study, the adhesive bond failed interfacially at relatively low load levels. DTIC

A STUDY OF INTERNAL DAMAGE OF METAL MATRIX COMPOSITES BY NEUTRON DIFFRACTION
N. Shi, M. A. M. Bourke, and J. A. Goldstone 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-7405-eng-36)
(DE95-005157; LA-UR-94-4246; CONF-941144-44) Avail: CASI HC A02/MF A01

Using neutron diffraction, we have measured the elastic phase strains of Al/TiC and Al/SiC composites under uniaxial tensile loading. The phase strains were used to reconstruct the global elastic strain. It has been found that, above macroscopic yield, the global elastic strain response is not linear. A theoretical model shows that the nonlinearity is dictated by changes in the ratio of longitudinal phase stresses. Furthermore, the changes in this ratio resulting from matrix plasticity and reinforcement fracture are different which leads to distinct slope changes in the global elastic strain response that can be used to distinguish the onset of these two processes on the global elastic strain loading curve. FATIGUE BEHAVIOR OF A CROSS-PLY CERAMIC MATRIX COMPOSITE SUBJECTED TO TENSION-TENSION CYCLING WITH HOLD TIME M.S. Thesis
Scott A. Grant Dec. 1994 138 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289418; AFIT/GAE/ENY/94D-16) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study was carried out to investigate the elevated temperature behavior of the SiC-MAS5 cross-ply (O/9O)4S ceramic matrix composite manufactured by Corning Inc. to fatigue with loading waveforms that combine the characteristics of stress rupture and high cycle fatigue. The test results were compiled in the form of S-N (cycles to failure), S-T (exposure time versus cycles to failure), S-S (energy exposure versus cycles to failure), normalized modulus degradation, strain progression, and hysteresis loop progression. From the mechanical behavior demonstrated by these curves, relationships between the effect of the environment and loading waveform were developed. In addition, a post-mortem SEM analysis of the fracture surface was conducted and the results compared to the mechanical behavior. DTIC

MODELING CONSIDERATIONS IN THE PREDICTION OF RESIDUAL STRENGTH IN COMPOSITE LAMINATES
Eric Saether Nov. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289128; ARL-MR-211) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The prediction of residual strength in damaged composite structures is complicated by the need to accurately characterize internal damage states and to mathematically simulate the material behavior which displays a variety of damage mechanisms and failure modes. Numerous analyses have been developed which, in general, have been restricted to specific damage modes and idealized geometric configurations. Modeling issues include micromechanical fiber/matrix failure phenomena, delamination growth, buckling of laminate sublayers, and nonlinear material and geometric response to applied loads. For the reliable design of composite components, the modeling approaches utilized in various specialized analyses need to be synthesized into a combined, robust methodology. The purpose of the present investigation is to identify the various salient failure phenomena involved in damaged composite laminates and to discuss mathematical modeling approaches to represent such damage. The identification of analytic approaches provides a basis for further extension to overcome existing limitations in the prediction of residual strength. DTIC

COMPOSITE PREPREG APPLICATION DEVICE Patent Application
Donald A. Sandusky, inventor (to NASA) (College of William and Mary, Williamsburg, VA.) and Joseph M. Marchello, inventor (to NASA) (Old Dominion Univ., Hampton, VA.) 21 Mar. 1995 14 p
(NASA-Case-LAR-15259-1; NAS 1.71:LAR-15259-1; US-Patent-Appl-SN-411231) Avail: CASI HC A03/MF A01

A heated shoe and cooled pressure roller assembly for composite prepreg application is provided. The shoe assembly includes a heated forward contact surface having a curved pressure surface. The following cooled roller provides a continuous pressure to the thermoplastic while reducing the temperature to approximately 5 C below glass transition temperature. Electric heating coils inside the forward portion of the shoe heat a thermoplastic workpiece to approximately 100 C above the glass transition. Immediately following the heated contact surface, a cooled roller cools the work. The end sharpened shape of the heated shoe trailing edge tends to prevent slag buildup and maintain a uniform, relaxed stress fabrication. NASA

MICROMECHANICAL MODELING OF DAMAGE AND INELASTICITY OF COMPOSITE MATERIALS IN MACROSCOPIC STRUCTURAL ANALYSIS
R. W. Macek, J. P. Gardner, and R. M. Hackett (Mississippi State Univ., Mississippi State, MS.) 1994 4 p Presented at the ASCE Engineering Mechanics Conference, Boulder, CO, 21-24 May 1995
(Contract W-7405-eng-36)
(DE95-003666; LA-UR-94-3960; CONF-9505115-1) Avail: CASI HC A01/MF A01

The method of cells has been extended to include damage or debonding between all adjacent subcells using a finite element formulation for the original cells assembly. Damage is implemented by placing a nonlinear three-dimensional spring between adjacent subcells. With this arrangement the damage is inherently anisotropic. The 'nonlinear substructure' cells finite element model is incorporated as a user defined material routine in a general purpose finite element code. The primary motivation for casting the method of cells as a finite element assemblage is to provide a composite constitutive model that facilitates the incorporation of various constituent material models, as well as any level of detail desired in the microstructure geometry. At present, the constituent material models may be anisotropic elastic or isotropic viscoelastic-plastic, while damage evolution is based on the macroscopic strain. The capability of the model is demonstrated through analyses of some simple structures loaded to failure. DOE

VARIATION OF SOLVENT SCATTERING-LENGTH DENSITY SMALL-ANGLE NEUTRON SCATTERING AS A MEANS OF DETERMINING STRUCTURE OF COMPOSITE MATERIALS
R. P. Hjelm, W. Wampler (Sid Richardson Carbon Co., Forth Worth, TX.), and M. Gerspacher (Sid Richardson Carbon Co., Forth Worth, TX.) 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-7405-eng-36)
(DE95-005394; LA-UR-94-4220; CONF-941144-40) Avail: CASI HC A02/MF A01

As part of our work on the structure of composite materials we have been exploring the use of small-angle neutron scattering using the method of contrast variation to dissect the component form, structure and distribution. This approach has resulted in a new look at a very old problem of reinforcement of elastomers by carbon black. Using this approach we studied an experimental high surface area (HSA) carbon black and a gel of 'HSA-bound' rubber in cyclohexane/deuterocyclohexane mixtures. HSA in cyclohexane is found to be short rodlike particle aggregates. The aggregates have a shell-core structure with a high density graphitic outer shell and an inner core of lower density amorphous carbon. The core is continuous throughout the carbon black aggregate, making the aggregate a stiff, integral unit. Contrast variation of swollen composite gels shows that there are two length scales in the gel structure. Above 10 (Angstrom), scattering from carbon black predominates, and below 10 (Angstrom) the scattering is from both carbon black and the elastomer. The HSA in the composite is completely embedded in polyisoprene. An estimate of the carbon black structure factor shows strong exclusion of neighboring aggregates, probably from excluded volume effects. The surface structure of the carbon black is unaltered by the interactions with elastomer and appears smooth over length scales above about 10 (Angstrom). These results show that contrast variation can provide information on composite structure that is not available by other means. This information relates to the reinforcement mechanism of elastomers by carbon blacks. DOE

THERMAL SHOCK BEHAVIOR OF FIBER-REINFORCED COMPOSITES
H. Wang, R. N. Singh, S. C. Beecher, and R. B. Dinwiddie 1995 12 p Presented at the 96th Annual Meeting and Exposition of the American Ceramic Society (ACerS), Indianapolis, IN, 24-28 Apr. 1995
(Contract DE-AC05-84OR-21400)
(DE95-006746; CONF-9504124-1) Avail: CASI HC A03/MF A01

The thermal shock behavior of three types of continuous fiber-reinforced ceramic composites (Nextel(trademark) or Nicalon(trademark) fiber-reinforced chemical vapor infiltrated or polymer-derived SiC matrix composites) was studied using the water quench technique. The thermal shock induced damage was characterized by both destructive and nondestructive techniques. As compared with monolithic ceramics, the continuous fiber-reinforced ceramic composites were capable of preventing catastrophic failure caused by thermal shock and were able to retain a significant portion of their original strength at Delta T = 1000 C. The nondestructive techniques involved measuring the thermal diffusivity by the flash technique and determining the Young's modulus by the dynamic resonance method. It has been demonstrated that these nondestructive techniques can detect damage induced by thermal shock and are more sensitive in detecting damage in the early stage than the conventional destructive technique of measuring the retained strength. DOE

STRESS TRANSFER FROM AXIALLY LOADED FIBER TO MATRIX IN A MICROCOMPOSITE
Chun-Hway Hsueh 1995 11 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007366; CONF-941144-69) Avail: CASI HC A03/MF A01

The shear lag model has been used extensively to analyze the stress transfer in a single fiber-reinforced composite (i.e., a microcomposite). To achieve analytical solutions, various simplifications have been adopted in the stress analysis. Questions regarding the adequacy of those simplifications are discussed in the present study for the following two cases: bonded interfaces and frictional interfaces. Specifically, simplifications regarding: (1) the radial dependences of axial stresses in the fiber and the matrix, and (2) Poisson's effect are addressed. For bonded interfaces, the latter can be ignored, and the former can generally be ignored. However, when the volume fraction of the fiber is high, the radial dependence of the axial stress in the fiber should be considered. For frictional interfaces, the former can be ignored, but the latter should be considered; however, it can be considered in an average sense to simplify the analysis. Comparisons among results obtained from analyses with various simplifications are made. DOE

EFFECTS OF HIGH-TEMPERATURE ENVIRONMENTS ON FLAW GENERATION AND FRACTURE BEHAVIOR OF SIC/SIC COMPOSITES
J. P. Singh and D. Singh Feb. 1995 8 p Presented at the 5th International Conference on the Science of Hard Materials, Maui, HI, 20-24 Feb. 1995
(Contract W-31-109-eng-38)
(DE95-008270; ANL/ET/CP-83155; CONF-950245-1) Avail: CASI HC A02/MF A01

Flaw generation and fracture behavior of Nicalon-fiber-reinforced SiC matrix composites are influenced by high temperatures. Therefore, the authors evaluated the effects of temperature by measuring the strength of these composites at several temperatures ranging from 800 to 1,300 C, and by characterizing their microstructure. While composite strength increased from approximately 400 MPa at room temperature to approximately 532 MPa at 800 C, it decreased to approximately 270 MPa at 1,300 C. Such degradation of composite strength at high temperature is believed to be partly due to fiber degradation. In-situ fiber strength of composites tested at room and elevated temperatures was estimated by fractographic techniques. The in-situ strength of fibers in composites was significantly lower than that of as-received fibers. This decrease is believed to be related to flaws that develop during processing and to exposure to elevated-temperature service environments. DOE

HIGH-TEMPERATURE DEFORMATION OF ZrO2-Al2O3/SiC WHISKER COMPOSITES FABRICATED BY TWO TECHNIQUES
J. M. CalderonMoreno (Seville Univ., Spain.), A. R. DeArellano-Lopez (Seville Univ., Spain.), A. Dominguez-Rodriguez (Seville Univ., Spain.), and J. L. Routbort 1995 17 p Presented at the 5th International Conference on the Science of Hard Materials, Maui, HI, 20-24 Feb. 1995
(Contract W-31-109-eng-38)
(DE95-008273; ANL/ET/CP-85762; CONF-950245-2) Avail: CASI HC A03/MF A01

ZrO2-Al2O3/SiC whisker-reinforced composites, with whisker volume fractions of 0 to 28%, fabricated both by powder and precursor processing, have been deformed at temperatures of 1300-1500 C under constant compression rates of 1.7 x 10(exp -5) to 6.8 x 10(exp -5) s(exp -1). Above 1400 C, a stress at which the work-hardening rate became zero could be measured and correlated with whisker content. On the other hand, at 1300 C all samples broke within the elastic regime. At 1350 C, increased whisker content appeared to inhibit fracture, so plastic behavior was obtained for samples containing 28% SiC. In the range of temperatures and compression rates, noted above, stress exponents were determined and tentatively correlated with microstructural features and their evolution during plastic deformation. DOE

TEM CHARACTERIZATION OF Al/Al2O3 COMPOSITE FABRICATED BY REACTIVE METAL INFILTRATION
Y. Gao, J. Jia, R. E. Loehman, and K. G. Ewsuk 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-AC04-94AL-85000; DE-AC04-76DP-00789)
(DE95-008508; SAND-95-0468C; CONF-941144-85) Avail: CASI HC A02/MF A01

The microstructure of Al/(alpha)-Al2O3 composites made by infiltrating Al into dense mullite preforms has been characterized using transmission electron microscopy. Observations revealed that the formation of the Al/Al2O3 composites involves three stages. Initially, Al infiltrates into a dense mullite preform through grain boundary diffusion, and reacts with mullite at grain boundaries to form a partial reaction zone. Then, a complete reaction takes place in the reaction region between the partial reaction zone and the full reaction zone to convert the dense mullite preform to a composite of (alpha)-Al2O3 (matrix) and an Al-Si phase (thin channels). Finally, the reduced Si from the reaction diffuses out of the Al/Al2O3 composite through the metal channels, whereas Al from the molten Al pool is continuously drawn to the reaction region until the mullite preform is consumed or the sample is removed from the molten Al pool. Based on the observed microstructure, infiltration mechanisms have been discussed, and a growth model of the composites is proposed in which the process involves repeated nucleation of Al2O3 grains and grain growth. DOE

FRACTURE TESTING AND ANALYSIS OF ADHESIVELY BONDED JOINTS FOR AUTOMOTIVE APPLICATIONS
Raymond G. Boeman and C. David Warren 1994 10 p Presented at the 10th Annual ASM/ESD Advanced Composites Conference, Dearborn, MI, 7-10 Nov. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007024; CONF-941195-1) Avail: CASI HC A02/MF A01

In 1992, the Oak Ridge National Laboratory (ORNL) began a cooperative effort with the Automotive Composites Consortium (ACC) to conduct research and development that would overcome technological hurdles to the adhesive bonding of current and future automotive materials. This effort is part of a larger Department of Energy (DOE) program to promote the use of lighter weight materials in automotive structures for the purpose of increasing fuel efficiency and reducing environmental pollutant emissions. In accomplishing this mission, the bonding of similar and dissimilar materials was identified as being of primary importance to the automotive industry since this enabling technology would give designers the freedom to choose from an expanded menu of low mass materials for component weight reduction. This paper concentrates on the details of developing accurate fracture test methods for adhesively bonded joints in the automotive industry. The test methods being developed are highly standardized and automated so that industry suppliers will be able to pass on reliable data to automotive designers in a timely manner. Mode I fracture tests have been developed that are user friendly and automated for easy data acquisition, data analysis, test control and test repeatability. The development of this test is discussed. In addition, materials and manufacturing issues are addressed which are of particular importance when designing adhesive and composite material systems. This publication contains the proceedings of the Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design held at Lake Tahoe, Nevada, during 4-7 Nov. 1991. Presentations were made in the following areas of composite structural design: perspectives in composites, design methodology, design applications, design criteria, supporting technology, damage tolerance, and manufacturing. For individual titles, see N95-28267 through N95-28293.

A precise control of composite material processing would not only improve part quality, but it would also directly reduce the overall manufacturing cost. The development and incorporation of sensors will help to generate real-time information for material processing relationships and equipment characteristics. In the present work, the thermocouple, pressure transducer, and dielectrometer technologies were investigated. The monitoring sensors were integrated with the computerized control system in three non-autoclave fabrication techniques: hot-press, self contained tool (self heating and pressurizing), and pressure vessel). The sensors were implemented in the parts and tools. Author

This paper describes the design and process development of low-cost structural parts made by a modified resin transfer molding process. Innovative application of elastomeric tooling to increase laminate fiber volume and automated forming of fiber preforms are discussed, as applied to fabrication of a representative section of a cruise missile fuselage. Resin Transfer Molding (RTM) has the potential of becoming one of the most cost effective ways of producing composite structures since the raw materials used, resin and dry fabric, are less costly than prepregs. Unfortunately these low material costs are offset by the high labor costs incurred to layup the dry fabric into 3D shapes. To reduce the layup costs, double diaphragm forming is being investigated as a potential technique for creating a complex 3D preform from a simple flat layup. As part of our effort to develop double diaphragm forming into a production capable process, we have undertaken a series of experiments to investigate the interactions between process parameters, mold geometry, fabric weave, tow size, and the quality of the formed part. The results of these tests will be used to determine the forming geometry limitations of double diaphragm forming and to characterize the formability of fabric configurations. An important part of this work was the development of methods to measure and analyze fiber orientations, deformation angles, tow spreading, and shape conformation of the formed parts. This paper will describe the methods used to mark plies, the double diaphragm forming process, the techniques used to measure the formed parts, and the calculation of the parameters of interest. The results can be displayed as 3D contour plots. These experimental results have also been used to verify and improve a computer model which simulates the draping of fabrics over 3D mold shapes. STATIC AND FATIGUE TESTING OF FULL-SCALE FUSELAGE PANELS FABRICATED USING A Therm-X(R) PROCESS
Albert J. DiNicola, Christos Kassapoglou, and Jack C. Chou *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 3 Sep. 1992 p 1185-1210 (For primary document see N95-28266 09-24)
(Contract NAS1-18799)
Copyright Avail: CASI HC A03/MF A04

Large, curved, integrally stiffened composite panels representative of an aircraft fuselage structure were fabricated using a Therm-X process, an alternative concept to conventional two-sided hard tooling and contour vacuum bagging. Panels subsequently were tested under pure shear loading in both static and fatigue regimes to assess the adequacy of the manufacturing process, the effectiveness of damage tolerant design features co-cured with the structure, and the accuracy of finite element and closed-form predictions of postbuckling capability and failure load. Test results indicated the process yielded panels of high quality and increased damage tolerance through suppression of common failure modes such as skin-stiffener separation and frame-stiffener corner failure. Finite element analyses generally produced good predictions of postbuckled shape, and a global-local modelling technique yielded failure load predictions that were within 7% of the experimental mean. The Hercules NASA ACT program was established to demonstrate and validate the low cost potential of the automated tow placement process for fabrication of aircraft primary structures. The program is currently being conducted as a cooperative program in collaboration with the Boeing ATCAS Program. The Hercules advanced tow placement process has been in development since 1982 and was developed specifically for composite aircraft structures. The second generation machine, now in operation at Hercules, is a production-ready machine that uses a low cost prepreg tow material form to produce structures with laminate properties equivalent to prepreg tape layup. Current program activities are focused on demonstration of the automated tow placement process for fabrication of subsonic transport aircraft fuselage crown quadrants. We are working with Boeing Commercial Aircraft and Douglas Aircraft during this phase of the program. The Douglas demonstration panels has co-cured skin/stringers, and the Boeing demonstration panel is an intricately bonded part with co-cured skin/stringers and co-bonded frames. Other aircraft structures that were evaluated for the automated tow placement process include engine nacelle components, fuselage pressure bulkheads, and fuselage tail cones. Because of the cylindrical shape of these structures, multiple parts can be fabricated on one two placement tool, thus reducing the cost per pound of the finished part. Author

Foster-Miller has developed a new process to provide through thickness reinforcement of composite structures. The process reinforces laminates locally or globally on-tool during standard autoclave processing cycles. Initial test results indicate that the method has the potential to significantly reduce delamination in carbon-epoxy. Laminates reinforced with the z-fiber process have demonstrated significant improvements in mode 1 fracture toughness and compression strength after impact. Unlike alternative methods, in-plane properties are not adversely affected. Author

McDonnell Aircraft Company (MCAIR) is teamed with Douglas Aircraft Company (DAC) under NASA's Advanced Composite Technology (ACT) initiative in a program entitled Innovative Composite Aircraft Primary Structures (ICAPS). Efforts at MCAIR have focused on the use of thermoplastic composite materials in the development of structural details associated with an advanced fighter fuselage section with applicability to transport design. Based on innovative design/manufacturing concepts for the fuselage section primary structure, elements were designed, fabricated, and structurally tested. These elements focused on key issues such as thick composite lugs and low cost forming of fastenerless, stiffener/moldline concepts. Manufacturing techniques included autoclave consideration, single diaphragm co-consolidation (SDCC), and roll-forming. Author

This Manufacturing Technology for Propulsion Program developed a process to produce a composite intermediate case for advanced gas turbine engines. The method selected to manufacture this large, complex part uses hard tooling for surfaces in the airflow path and trapped rubber to force the composite against the mold. Subelements were manufactured and tested to verify the selected design, tools, and processes. The most significant subelement produced was a half-scale version of a composite intermediate case. The half-scale subelement maintained the geometry and key dimensions of the full-scale case, allowing relevant process development and structural verification testing to be performed on the subelement before manufacturing the first full-scale case. The NASA LaRC is conducting and supporting research to develop cost-effective fabrication methods that are applicable to primary composite aircraft structures. One of the most promising fabrication methods that has evolved is resin transfer molding (RTM) of dry textile material forms. RTM has been used for many years for secondary structures, but has received increased emphasis because it is an excellent method for applying resin to damage-tolerant textile preforms at low cost. Textile preforms based on processes such as weaving, braiding, knitting, stitching, and combinations of these have been shown to offer significant improvements in damage tolerance compared to laminated tape composites. The use of low-cost resins combined with textile preforms could provide a major breakthrough in achieving cost-effective composite aircraft structures. RTM uses resin in its lowest cost form, and storage and spoilage costs are minimal. Near net shape textile preforms are expected to be cost-effective because automated machines can be used to produce the preforms, post-cure operations such as machining and fastening are minimized, and material scrap rate may be reduced in comparison with traditional prepreg molding. The purpose of this paper is to discuss experimental and analytical techniques that are under development at NASA Langley to aid the engineer in developing RTM processes for airframe structural elements. Included are experimental techniques to characterize preform and resin behavior and analytical methods that were developed to predict resin flow and cure kinetics. Author

ANALYSIS OF AIRCRAFT ENGINE BLADE SUBJECT TO ICE IMPACT c07
E. S. Reddy (Sverdrup Technology, Inc., Brook Park, OH.), G. H. Abumeri (Sverdrup Technology, Inc., Brook Park, OH.), C. C. Chamis, and P. L. N. Murthy *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 3 Sep. 1992 p 1319-1331 Previously announced as N92-15402 (For primary document see N95-28266 09-24)
Copyright Avail: CASI HC A03/MF A04

The ice impact problem on an engine blade made of layered composite is simulated. The ice piece is modeled as an equivalent spherical object and has the velocity opposite to that of the aircraft with direction parallel to the engine axis. Near the impact region and along the leading edge, the blade is assumed to be fully stressed and undergoes large deflection. A specified portion of the blade around the impact region is modeled. The effect of ice size and velocity on the average leading edge strain are investigated for a modified SR-2 model unswept composite propfan blade. Parametric studies are performed to study the response due to ice impact at various locations along the span. Also, the effects of engine speed on the strain and impact displacements are discussed. It is found that for a given engine speed, a critical ice speed exists that corresponds to the maximum strain and this critical speed increases with increase in the engine speed. Author

APPLICATION OF FIBER-REINFORCED BISMALEIMIDE MATERIALS TO AIRCRAFT NACELLE STRUCTURES c05
Vasilios Peros, John Ruth, and David Trawinski *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 3 Sep. 1992 p 1333-1347 (For primary document see N95-28266 09-24)

Existing aircraft engine nacelle structures employ advanced composite materials to reduce weight and thereby increase overall performance. Use of advanced composite materials on existing aircraft nacelle structures includes fiber-reinforced epoxy structures and has typically been limited to regions furthest away from the hot engine core. Portions of the nacelle structure that are closer to the engine require materials with a higher temperature capability. In these portions, existing nacelle structures employ aluminum sandwich construction and skin/stringer construction. The aluminum structure is composed of many detail parts and assemblies and is usually protected by some form of ablative, insulator, or metallic thermal shield. A one-piece composite inner cowl for a new-generation engine nacelle structure has been designed using fiber-reinforced bismaleimide (BMI) materials and honeycomb core in a sandwich construction. The new composite design has many advantages over the existing aluminum structure. Multiple details were integrated into the one-piece composite design, thereby significantly reducing the number of detail parts and fasteners. The use of lightweight materials and the reduction of the number of joints result in a significant weight reduction over the aluminum design; manufacturing labor and the overall number of tools required have also been reduced. Several significant technical issues were addressed in the development of a BMI composite design. Technical evaluation of the available BMI systems led to the selection of a toughened BMI material which was resistant to microcracking under thermal cyclic loading and enhanced the damage tolerance of the structure. Technical evaluation of the degradation of BMI materials in contact with aluminum and other metals validated methods for isolation of the various materials. Graphite-reinforced BMI in contact with aluminum and some steels was found to degrade in salt spray testing. Isolation techniques such as those used for graphite-reinforced epoxy structures were shown to provide adequate protection. The springback and producibility of large BMI structures were evaluated by manufacturing prototype hardware which had the full-scale cross section of the one-piece composite structure. Author

Experimental and analytical studies of the development of delaminations around fastener holes in composite structures are presented. This type of delamination is known to occur in composite skins that are mechanically fastened to a poorly mating substructure. Results of an experimental study to determine the resistance of laminates to the initiation of assembly induced delaminations and the residual strength of assembly damaged coupons are presented for AS4/3501-6, IM7/8551-7A, and AS4/PEEK material systems. A survey of existing analytical models for predicting the residual strength and stability of delaminations is presented, and the development of a new model for predicting the initiation of delaminations around a fastener hole is outlined. The fastener hole damage initiation model utilizes a finite element based Fourier series solution, and is validated through comparisons of analytical and experimental results. Author

This paper presents a nonlinear stress analysis of a thick-walled compound tube subjected to internal pressure. The compound tube is constructed of a steel liner and a graphite-bismaleimide outer shell. Analytical expressions for the stresses, strains, and displacements are derived for all loading ranges up to failure. Numerical results for the stresses and the maximum value that the compound tube can contain without failure are presented. Author

The composite actuator is 'jam resistant', satisfying a survivability requirement for the Navy. Typically, the push-pull force needed to drive through the wound area of the composite actuator is 73 percent less than that of an all-metal actuator. In addition to improving the aircraft's combat survivability, significant weight savings were realized. The current design of the survivable, composite actuator cylinder is 36 percent lighter than that of the production steel cylinder, which equates to a 15 percent overall actuator weight savings. Copyright Avail: CASI HC A02/MF A04

A higher order, sub-parametric, laminated, 3D solid finite element was used for the analysis of very thick laminated composite plates. The geometry of this element is defined by four nodes in the X-Y plane which define a prism of material through the thickness of the laminate. There are twenty-four degrees of freedom at each node; translations at the upper and lower surfaces of the laminate in each of the three coordinate directions, and the derivatives of these translations with respect to each coordinate. This choice of degrees of freedom leads to displacement and strain compatibility at the corners. Stacking sequence effects are accounted for by explicitly integrating the strain energy density through the thickness of the element. The laminated solid element was combined with a gap-contact element to analyze thick laminated composite lugs loaded through flexible pins. The resulting model accounts for pin bending effects that produce non-uniform bearing stresses through the thickness of the lug. A thick composite lug experimental test program was performed, and provided data that was used to validate the analytical model. Two lug geometries and three stacking sequences were tested. Author

AN IMPROVED PLATE THEORY OF ORDER (1,2) FOR THICK COMPOSITE LAMINATES
A. Tessler *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 3 Sep. 1992 p 1417-1430 (For primary document see N95-28266 09-24)
Copyright Avail: CASI HC A03/MF A04

A new (1,2)-order theory is proposed for the linear elasto-static analysis of laminated composite plates. The basic assumptions are those concerning the distribution through the laminate thickness of the displacements, transverse shear strains and the transverse normal stress, with these quantities regarded as some weighted averages of their exact elasticity theory representations. The displacement expansions are linear for the inplane components and quadratic for the transverse component, whereas the transverse shear strains and transverse normal stress are respectively quadratic and cubic through the thickness. The main distinguishing feature of the theory is that all strain and stress components are expressed in terms of the assumed displacements prior to the application of a variational principle. This is accomplished by an a priori least-square compatibility requirement for the transverse strains and by requiring exact stress boundary conditions at the top and bottom plate surfaces. Equations of equilibrium and associated Poisson boundary conditions are derived from the virtual work principle. It is shown that the theory is particularly suited for finite element discretization as it requires simple C(sup 0)- and C(sup -1)-continuous displacement interpolation fields. Analytic solutions for the problem of cylindrical bending are derived and compared with the exact elasticity solutions and those of our earlier (1,2)-order theory based on the assumed displacements and transverse strains. FAILURE ANALYSIS OF THICK COMPOSITE CYLINDERS UNDER EXTERNAL PRESSURE c39
A. Caiazzo and B. W. Rosen *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 3 Sep. 1992 p 1431-1446 Prepared for ORNL, TN; and Martin Marietta Energy Systems, Inc., Oak Ridge, TN (For primary document see N95-28266 09-24)
Copyright Avail: CASI HC A03/MF A04

Failure of thick section composites due to local compression strength and overall structural instability is treated. Effects of material nonlinearity, imperfect fiber architecture, and structural imperfections upon anticipated failure stresses are determined. Comparisons with experimental data for a series of test cylinders are described. Predicting the failure strength of composite structures requires consideration of stability and material strength modes of failure using linear and nonlinear analysis techniques. Material strength prediction requires the accurate definition of the local multiaxial stress state in the material. An elasticity solution for the linear static analysis of thick anisotropic cylinders and rings is used herein to predict the axisymmetric stress state in the cylinders. Asymmetric nonlinear behavior due to initial cylinder out of roundness and the effects of end closure structure are treated using finite element methods. It is assumed that local fiber or ply waviness is an important factor in the initiation of material failure. An analytical model for the prediction of compression failure of fiber composites, which includes the effects of fiber misalignments, matrix inelasticity, and multiaxial applied stresses is used for material strength calculations. Analytical results are compared to experimental data for a series of glass and carbon fiber reinforced epoxy cylinders subjected to external pressure. Recommendations for pretest characterization and other experimental issues are presented. Implications for material and structural design are discussed. Author

A method for analyzing biaxial- and shear-loaded anisotropic rectangular panels with centrally located circular and elliptical cutouts is presented in the present paper. The method is based on Lekhnitskii's complex variable equations of plane elastostatics combined with a boundary collocation method and a Laurent series approximation. Results are presented for anisotropic panels with elliptical cutouts and subjected to combined shear and compression loading. The effects on the stress field of panel aspect ratio, anisotropy, cutout size, and cutout orientation are addressed. Angle-ply laminates, unidirectional off-axis laminates, and ((+ or - 45/0/90)(sub 3))s, ((+ or - 45/0(sub 2))(sub 3))s, and ((+ or - 45/90(sub 2))(sub 3))s laminates are examined. Author

The irrelevance of most composite failure criteria to conventional fiber-polymer composites is claimed to have remained undetected primarily because the experiments that can either validate or disprove them are difficult to perform. Uniaxial tests are considered inherently incapable of validating or refuting any composite failure theory because so much of the total load is carried by the fibers aligned in the direction of the load. The Ten-Percent Rule, a simple rule-of-mixtures analysis method, is said to work well only because of this phenomenon. It is stated that failure criteria can be verified for fibrous composites only by biaxial tests, with orthogonal in-plane stresses of the same as well as different signs, because these particular states of combined stress reveal substantial differences between the predictions of laminate strength made by various theories. Three scientifically plausible failure models for fibrous composites are compared, and it is shown that only the in-plane shear test (orthogonal tension and compression) is capable of distinguishing between them. This is because most theories are 'calibrated' against the measured uniaxial tension and compression tests and any cross-plied laminate tests dominated by those same states of stress must inevitably 'confirm' the theory. STATIC AND DYNAMIC STRAIN ENERGY RELEASE RATES IN TOUGHENED THERMOSETTING COMPOSITE LAMINATES **c39**
Douglas S. Cairns *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 3 Sep. 1992 p 1529-1538 Previously announced in IAA as A92-37000 (For primary document see N95-28266 09-24)
Copyright Avail: CASI HC A02/MF A04

In this work, the static and dynamic fracture properties of several thermosetting resin based composite laminates are presented. Two classes of materials are explored. These are homogeneous, thermosetting resins and toughened, multi-phase, thermosetting resin systems. Multi-phase resin materials have shown enhancement over homogenous materials with respect to damage resistance. The development of new dynamic tests are presented for composite laminates based on Width Tapered Double Cantilevered Beam (WTDCB) for Mode 1 fracture and the End Notched Flexure (ENF) specimen. The WTDCB sample was loaded via a low inertia, pneumatic cylinder to produce rapid cross-head displacements. A high rate, piezo-electric load cell and an accelerometer were mounted on the specimen. A digital oscilloscope was used for data acquisition. Typical static and dynamic load versus displacement plots are presented. The ENF specimen was impacted in three point bending with an instrumented impact tower. Fracture initiation and propagation energies under static and dynamic conditions were determined analytically and experimentally. The test results for Mode 1 fracture are relatively insensitive to strain rate effects for the laminates tested in this study. The test results from Mode 2 fracture indicate that the toughened systems provide superior fracture initiation and higher resistance to propagation under dynamic conditions. While the static fracture properties of the homogeneous systems may be relatively high, the apparent Mode 2 dynamic critical strain energy release rate drops significantly. The results indicate that static Mode 2 fracture testing is inadequate for determining the fracture performance of composite structures subjected to conditions such as low velocity impact. A good correlation between the basic Mode 2 dynamic fracture properties and the performance is a combined material/structural Compression After Impact (CAI) test is found. These results underscore the importance of examining rate-dependent behavior for determining the longevity of structures manufactured from composite materials. Author

Two finite element analysis codes are used to model the effects of cooling on the dimensional stability of formed and bonded composite parts. The two analysis routines, one h-version and one p-version, are compared for modeling time, analysis execution time, and exactness of solution as compared to actual test results. A recommended procedure for predicting temperature effects on composite parts is presented, based on the results of this study. Author

This paper presents a deterministic procedure for tailoring the continuum stiffness and strength of uniform space-filling truss structures through the appropriate selection of truss geometry and member sizes (i.e., flexural and axial stiffnesses and length). The trusses considered herein are generated by replication of a characteristic truss cell uniformly through space. The repeating cells are categorized by one of a set of possible geometric symmetry groups derived using the techniques of crystallography. The elastic symmetry associated with each geometric symmetry group is identified to aid in the selection of an appropriate truss geometry for a given application. Stiffness and strength tailoring of a given truss geometry is enabled through explicit expressions relating the continuum stiffnesses and failure stresses of the truss to the stiffnesses and failure loads of its members. These expressions are derived using an existing equivalent continuum analysis technique and a newly developed analytical failure theory for trusses. Several examples are presented to illustrate the application of these techniques, and to demonstrate the usefulness of the information gained from this analysis. Author

Extensive stress rupture studies on glass composites and Kevlar composites were conducted by the Lawrence Radiation Laboratory beginning in the late 1960's and extending to about 8 years in some cases. Some of the data from these studies published over the years were incomplete or were tainted by spurious failures, such as grip slippage. Updated data sets were defined for both fiberglass and Kevlar composite stand test specimens. These updated data are analyzed in this report by a convenient form of the bivariate Weibull distribution, to establish a consistent set of design prediction charts that may be used as a conservative basis for predicting the stress rupture life of composite pressure vessels. The updated glass composite data exhibit an invariant Weibull modulus with lifetime. The data are analyzed in terms of homologous service load (referenced to the observed median strength). The equations relating life, homologous load, and probability are given, and corresponding design prediction charts are presented. A similar approach is taken for Kevlar composites, where the updated stand data do show a turndown tendency at long life accompanied by a corresponding change (increase) of the Weibull modulus. The turndown characteristic is not present in stress rupture test data of Kevlar pressure vessels. A modification of the stress rupture equations is presented to incorporate a latent, but limited, strength drop, and design prediction charts are presented that incorporate such behavior. The methods presented utilize Cartesian plots of the probability distributions (which are a more natural display for the design engineer), based on median normalized data that are independent of statistical parameters and are readily defined for any set of test data. To study the influence on overall deformations of the time-dependent constitutive properties of fiber-reinforced polymeric matrix composite materials being considered for use in orbiting precision segmented reflectors, simple sandwich beam models are developed. The beam models include layers representing the face sheets, the core, and the adhesive bonding of the face sheets to the core. A three-layer model lumps the adhesive layers with the face sheets or core, while a five-layer model considers the adhesive layers explicitly. The deformation response of the three-layer and five-layer sandwich beam models to a midspan point load is studied. This elementary loading leads to a simple analysis, and it is easy to create this loading in the laboratory. Using the correspondence principle of viscoelasticity, the models representing the elastic behavior of the two beams are transformed into time-dependent models. Representative cases of time-dependent material behavior for the facesheet material, the core material, and the adhesive are used to evaluate the influence of these constituents being time-dependent on the deformations of the beam. As an example of the results presented, if it assumed that, as a worst case, the polymer-dominated shear properties of the core behave as a Maxwell fluid such that under constant shear stress the shear strain increases by a factor of 10 in 20 years, then it is shown that the beam deflection increases by a factor of 1.4 during that time. In addition to quantitative conclusions, several assumptions are discussed which simplify the analyses for use with more complicated material models. Finally, it is shown that the simpler three-layer model suffices in many situations. Author

A composite flexible blanket insulation (CFBI) system considered for use as a thermal protection system for space vehicles is described. This flexible composite insulation system consists of an outer layer of silicon carbide fabric, followed by alumina mat insulation, and alternating layers of aluminized polyimide film and aluminoborosilicate scrim fabric. A potential application of this composite insulation would be as a thermal protection system for the aerobrake of the Aeroassist Space Transfer Vehicle (ASTV). It would also apply to other space vehicles subject to high convective and radiative heating during atmospheric entry. The thermal performance of this composite insulation as exposed to a simulated atmospheric entry environment in a plasma arc test facility is described. Other thermophysical properties which affect the thermal response of this system are also described. Analytical modeling describing the thermal performance of this composite insulation is included. It shows that this composite insulation is effective as a thermal protection system at total heating rates up to 30.6 W/sq cm. Author

UTILIZATION OF COMPOSITE MATERIALS BY THE US ARMY: A LOOK AHEAD
Richard Chait *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 7-34 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

An overview of the use of composite materials in the Army is given. Important efforts to document design information, supporting research, and some national applications for composite materials are given. The use of Kevlar fiber in both vests and helmets for the soldier is outlined. The advantages of using fiberglass in the hull of the Bradley fighting ground vehicle is given. The full potential of composite materials is realized in the recently awarded LH Comanche RAH-66 program. The use of composites for application to rocket motor uses, wings, fins, and casings is under development. Because of the uncertain funding profile, it is more important than ever that technology planning provide the basis for effective prioritization and leveraging of the tech base efforts involving advanced materials. There are many unique aspects of Navy air missions that lead to the differentiation between the design and performance of ship and shore-based aircraft. The major aspects are discussed from which essentially all Navy aircraft design requirements derive. (1) Navy aircraft operate from carriers at sea imposes a broad spectrum of physical conditions, constraints, and requirements ranging from the harsh sea environment, the space limitations of a carrier, takeoff and landing requirements as well as for endurance at long distances from the carrier. (2) Because the carrier and its airwing are intended to be capable of responding to a broad range of contingencies, mission flexibility is essential (maximum weapon carriage, rapid reconfiguration, multiple mission capability). (3) The embarked aircraft provides the long range defense of the battle group against air, surface and subsurface launched antiship missiles. (4) The carrier and its aircraft must operate independently and outside of normal supply lines. Taking into account these aspects, the use of composite materials in the design and performance of naval aircraft is outlined, also listing advantages and disadvantages. Author

MECHANICAL PROPERTIES OF TRIAXIALLY BRAIDED COMPOSITES: EXPERIMENTAL AND ANALYTICAL RESULTS
John E. Masters, Raymond L. Foye (North Carolina Agricultural and Technical State Univ., Greensboro, NC.), Christopher M. Pastore (North Carolina Univ., Raleigh, NC.), and Yasser A. Gowayed (North Carolina Univ., Raleigh, NC.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 99-124 Previously announced as N92-19725 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

The unnotched tensile properties of 2-D triaxial braid reinforced composites from both an experimental and an analytical viewpoint are studied. The materials are graphite fibers in an epoxy matrix. Three different reinforcing fiber architectures were considered. Specimens were cut from resin transfer molded (RTM) composite panels made from each braid. There were considerable differences in the observed elastic constants from different size strain gage and extensometer reading. Larger strain gages gave more consistent results and correlated better with the extensometer reading. Experimental strains correlated reasonably well with analytical predictions in the longitudinal, 0 degrees, fiber direction but not in the transverse direction. Tensile strength results were not always predictable even in reinforcing directions. Minor changes in braid geometry led to disproportionate strength variations. The unit cell structure of the triaxial braid was discussed with the assistance of computer analysis of the microgeometry. Photomicrographs of braid geometry were used to improve upon the computer graphics representations of unit cells. These unit cells were used to predict the elastic moduli with various degrees of sophistication. The simple and the complex analyses were generally in agreement but none adequately matched the experimental results for all the braids. Author

MECHANISMS OF COMPRESSIVE FAILURE IN WOVEN COMPOSITES AND STITCHED LAMINATES
B. N. Cox, M. S. Dadkhah, R. V. Inman, W. L. Morris, and S. Schroeder *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 125-13 (For primary document see N95-28420 09-24)
(Contract NAS1-18840)
Avail: CASI HC A03/MF A04

Stitched laminates and angle interlock woven composites have been studied in uniaxial, in-plane, monotonic compression. Failure mechanisms have been found to depend strongly on both the reinforcement architecture and the degree of constraint imposed by the loading grips. Stitched laminates show higher compressive strength, but are brittle, possessing no load bearing capacity beyond the strain for peak load. Post-mortem inspection shows a localized shear band of buckled and broken fibers, which is evidently the product of an unstably propagating kink band. Similar shear bands are found in the woven composites if the constraint of lateral displacements is weak; but, under strong constraint, damage is not localized but distributed throughout the gauge section. While the woven composites tested are weaker than the stitched laminates, they continue to bear significant loads to compressive strains of approx. 15 percent, even when most damage is confined to a shear band. EFFECT OF THE FIBER-MATRIX INTERPHASE ON THE TRANSVERSE TENSILE STRENGTH OF THE UNIDIRECTIONAL COMPOSITE MATERIAL

H. C. Tsai and A. M. Arocho *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 139-15 (For primary document see N95-28420 09-24)

Avail: CASI HC A03/MF A04

A simple one-dimensional fiber-matrix interphase model has been developed and analytical results obtained correlated well with available experimental data. It was found that by including the interphase between the fiber and matrix in the model, much better local stress results were obtained than with the model without the interphase. A more sophisticated two-dimensional micromechanical model, which included the interphase properties was also developed. Both one-dimensional and two-dimensional models were used to study the effect of the interphase properties on the local stresses at the fiber, interphase and matrix. From this study, it was found that interphase modulus and thickness have significant influence on the transverse tensile strength and mode of failure in fiber reinforced composites. Author

THE EFFECT OF MATERIAL HETEROGENEITY IN CURVED COMPOSITE BEAMS FOR USE IN AIRCRAFT STRUCTURES

Brendan J. OToole and Michael H. Santare *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 157-16 (For primary document see N95-28420 09-24)

(Contract NAS1-18758)

Avail: CASI HC A02/MF A04

A design tool is presented for predicting the effect of material heterogeneity on the performance of curved composite beams for use in aircraft fuselage structures. Material heterogeneity can be induced during processes such as sheet forming and stretch forming of thermoplastic composites. This heterogeneity can be introduced in the form of fiber realignment and spreading during the manufacturing process causing a gradient in material properties in both the radial and tangential directions. The analysis procedure uses a separate two-dimensional elasticity solution for the stresses in the flanges and web sections of the beam. The separate solutions are coupled by requiring the forces and displacements match at the section boundaries. Analysis is performed for curved beams loaded in pure bending and uniform pressure. The beams can be of any general cross-section such as a hat, T-, I-, or J-beam. Preliminary results show that geometry of the beam dictates the effect of heterogeneity on performance. Heterogeneity plays a much larger role in beams with a small average radius to depth ratio, R/t, where R is the average radius of the beam and t is the difference between the inside and outside radius. Results of the analysis are in the form of stresses and displacements, and they are compared to both mechanics of materials and numerical solutions obtained using finite element analysis. Author

INVESTIGATION OF STATIC AND CYCLIC BEARING FAILURE MECHANISMS FOR GR/EP LAMINATES

R. W. Walter and M. M. Tuttle *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 167-18 (For primary document see N95-28420 09-24)

Avail: CASI HC A03/MF A04

Static, cyclic load (fatigue), and residual strength testing of graphite-epoxy (GR/EP) and aluminum pin bearing joints was completed to study bearing failure mechanisms. Parameters investigated included static strength, failure mode, fatigue life, hole growth, joint stiffness, and residual strength. Comparative evaluation of these results show that the MIL-HDBK-5 convention for the definition of bearing strength can be used for GR/EP materials while maintaining the same, or improved, level of structural integrity shown for metal joints. COMPRESSION FAILURE OF ANGLE-PLY LAMINATES

L. D. Peel (Mirage Carriage Works, West Valley, UT.), M. W. Hyer (Virginia Polytechnic Inst. and State Univ., Blacksburg, VA.), and M. J. Shuart *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 185-19 (For primary document see N95-28420 09-24)

(Grant NAG1-343)

Avail: CASI HC A03/MF A04

Test results from the compression loading of (+ or - Theta/ - or + Theta)(sub 6s) angle-ply IM7-8551-7a specimens, 0 less than or = Theta less than or = 90 degs, are presented. The observed failure strengths and modes are discussed, and typical stress-strain relations shown. Using classical lamination theory and the maximum stress criterion, an attempt is made to predict failure stress as a function of Theta. This attempt results in poor correlation with test results and thus a more advanced model is used. The model, which is based on a geometrically nonlinear theory, and which was taken from previous work, includes the influence of observed layer waviness. The waviness is described by the wave length and the wave amplitude. The theory is briefly described and results from the theory are correlated with test results. It is shown that by using levels of waviness observed in the specimens, the correlation between predictions and observations is good. Author

ANALYSIS OF COMPOSITE STRUCTURES WITH DELAMINATIONS UNDER COMBINED BENDING AND COMPRESSION

Han-Pin Kan, Edward Kautz (Naval Air Development Center, Warminster, PA.), and Larry Neri (Federal Aviation Administration, Atlantic City, NJ.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 197-21 (For primary document see N95-28420 09-24)

(Contract N62269-90-C-0282)

Avail: CASI HC A03/MF A04

A methodology had been developed for strength prediction of composite structures with delaminations under combined bending and compression loads. The methodology is an extension of the delamination analysis method developed under the USAF/Boeing/Northrop 'Damage Tolerance of Composites' program. Delamination buckling and strain energy release rate analyses are used as basic tools in the strength prediction. In addition, failure mode interaction and structural configuration effects are considered. The influence of fasteners on the strength of a delaminated structure is incorporated to evaluate assembly-caused delaminations. The capabilities and limitations of the analysis method are shown by correlating the analytical results with the existing experimental data. The failure load, failure mode and failure sequence of a structure containing delaminations are predicted and the analytical results are compared with test data. Author

BUCKLING BEHAVIOR OF LONG SYMMETRICALLY LAMINATED PLATES SUBJECTED TO COMBINED LOADS

Michael P. Nemeth *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 227-25 Previously announced as N92-25160 (For primary document see N95-28420 09-24)

Avail: CASI HC A03/MF A04

A parametric study of the buckling behavior of infinitely long symmetrically laminated anisotropic plates subjected to combined loadings is presented. The loading conditions considered are axial tension and compression, transverse tension and compression, and shear. Results obtained using a special purpose analysis, well suited for parametric studies are presented for clamped and simply supported plates. Moreover, results are presented for some common laminate constructions, and generic buckling design charts are presented for a wide range of parameters. The generic design charts are presented in terms of useful nondimensional parameters, and dependence of the nondimensional parameters on laminate fiber orientation, stacking sequence, and material properties is discussed. An important finding of the study is that the effects of anisotropy are much more pronounced in shear-loaded plates than in compression loaded plates. In addition, the effects of anisotropy on plates subjected to combined loadings are generally manifested as a phase shift of self-similar buckling interaction curves. A practical application of this phase shift is the buckling resistance of long plates can be improved by applying a shear loading with a specific orientation. In all cases considered, it is found that the buckling coefficients of infinitely long plates are independent of the bending stiffness ratio (D sub 11/D sub 22) sup 1/4. Author

COMPRESSIVE RESIDUAL STRENGTH OF GRAPHITE/EPOXY LAMINATES AFTER IMPACT

Teresa A. Guy and Paul A. Lagace *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 253-27 (For primary document see N95-28420 09-24)

Avail: CASI HC A03/MF A04

The issue of damage tolerance after impact, in terms of the compressive residual strength, was experimentally examined in graphite/epoxy laminates using Hercules AS4/3501-6 in a (+ or - 45/0)(sub 2S) configuration. Three different impactor masses were used at various velocities and the resultant damage measured via a number of nondestructive and destructive techniques. Specimens were then tested to failure under uniaxial compression. The results clearly show that a minimum compressive residual strength exists which is below the open hole strength for a hole of the same diameter as the impactor. Increases in velocity beyond the point of minimum strength cause a difference in the damage produced and cause a resultant increase in the compressive residual strength which asymptotes to the open hole strength value. Furthermore, the results show that this minimum compressive residual strength value is independent of the impactor mass used and is only dependent upon the damage present in the impacted specimen which is the same for the three impactor mass cases. A full 3-D representation of the damage is obtained through the various techniques. Only this 3-D representation can properly characterize the damage state that causes the resultant residual strength. Assessment of the state-of-the-art in predictive analysis capabilities shows a need to further develop techniques based on the 3-D damage state that exists. In addition, the need for damage 'metrics' is clearly indicated. Author

APPLICATION OF ADVANCED MATERIAL SYSTEMS TO COMPOSITE FRAME ELEMENTS

Steven Llorente, Pierre Minguet, Russell Fay, and Steven Medwin (Du Pont de Nemours, E. I. and Co., Wilmington, DE.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 277-29 (For primary document see N95-28420 09-24)

Avail: CASI HC A03/MF A04

A three phase program has been conducted to investigate DuPont's Long Discontinuous Fiber (LDF) composites. Additional tests were conducted to compare LDF composites against toughened thermosets and a baseline thermoset system. Results have shown that the LDF AS4/PEKK offers improved interlaminar (flange bending) strength with little reduction in mechanical properties due to the discontinuous nature of the fibers. In the third phase, a series of AS4/PEKK LDF C-section curved frames (representing a typical rotorcraft light frame) were designed, manufactured and tested. Specimen reconsolidation after 'stretch forming' and frame thickness were found to be key factors in this light frame's performance. A finite element model was constructed to correlate frame test results with expected strain levels determined from material property tests. Adequately reconsolidated frames performed well and failed at strain levels at or above baseline thermoset material test strains. Finally a cost study was conducted which has shown that the use of LDF for this frame would result in a significant cost savings, for moderate to large lot sizes compared with the hand lay-up of a thermoset frame. DESIGN, ANALYSIS, AND TESTING OF A METAL MATRIX COMPOSITE WEB/FLANGE INTERSECTION

S. B. Biggers (Clemson Univ., SC.), N. F. Knight, Jr. (Clemson Univ., SC.), S. G. Moran, and R. Olliffe (Lockheed Aeronautical Systems Co., Marietta, GA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 297-32 (For primary document see N95-28420 09-24)

Avail: CASI HC A03/MF A04

An experimental and analytical program to study the local design details of a typical T-shaped web/flange intersection made from a metal matrix composite is described. Loads creating flange bending were applied to specimens having different designs and boundary conditions. Finite element analyses were conducted on models of the test specimens to predict the structural response. The analyses correctly predict failure load, mode, and location in the fillet material in the intersection region of the web and the flange when specimen quality is good. The test program shows the importance of fabrication quality in the intersection region. The full-scale test program that led to the investigation of this local detail is also described. Author

Avail: CASI HC A03/MF A04

Tough resin is needed to resist delamination crack propagation. However, modulus often has to be compromised because it is difficult to retain both high modulus and toughness in a matrix material. A potential solution is to use a hybrid system in which tough resin strips are included within a conventional matrix composite. By adjusting the spacing of the tough resin strips, maximum delamination size can be controlled. Experimental results for impact damage and subsequent damage propagation in laminates containing tough resin strips are reported. Plain adhesive strips and fiber-reinforced tough resin composite strips were used in constructing the hybrid laminates. Test results indicated that size of delamination inflicted by impact was confined between the tough resin strips. As a result, significantly increased residual compressive strength was obtained. Impacted laminates containing tough resin strips were also fatigue tested. It was found that these strips reduced the growth of the impact damage area relative to the growth seen in coupons with no tough resin strips. Damage growth from an open hole under tension fatigue was evaluated using both tough resin strips and glass fiber reinforced tough resin strips. Unreinforced tough resin strips retarded delamination growth from the open hole, but did not stop matrix cracks growing in the fiber direction. Fiber reinforced tough resin strips did not contain axial delamination growth from the open hole. However, they did act as crack arresters, stopping the through-the-thickness tension crack originating from the hole. Author

VIBRATIONAL BEHAVIOR OF ADAPTIVE AIRCRAFT WING STRUCTURES MODELLED AS COMPOSITE THIN-WALLED BEAMS

O. Song, L. Librescu, and C. A. Rogers *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 361-38 (For primary document see N95-28420 09-24)

(Contract N00014-88-C-0721)

Avail: CASI HC A03/MF A04

The vibrational behavior of cantilevered aircraft wings modeled as thin-walled beams and incorporating piezoelectric effects is studied. Based on the converse piezoelectric effect, the system of piezoelectric actuators conveniently located on the wing yield the control of its associated vertical and lateral bending eigenfrequencies. The possibility revealed by this study enabling one to increase adaptively the eigenfrequencies of thin-walled cantilevered beams could play a significant role in the control of the dynamic response and flutter of wing and rotor blade structures. Author

UNIQUE CONSIDERATIONS IN THE DESIGN AND EXPERIMENTAL EVALUATION OF TAILORED WINGS WITH ELASTICALLY PRODUCED CHORDWISE CAMBER
Lawrence W. Rehfield, Peter J. Zischka, Michael L. Fentress, and Stephen Chang *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 383-40 (For primary document see N95-28420 09-24)
(Contract NAS1-18754)
Avail: CASI HC A03/MF A04

Some of the unique considerations that are associated with the design and experimental evaluation of chordwise deformable wing structures are addressed. Since chordwise elastic camber deformations are desired and must be free to develop, traditional rib concepts and experimental methodology cannot be used. New rib design concepts are presented and discussed. An experimental methodology based upon the use of a flexible sling support and load application system has been created and utilized to evaluate a model box beam experimentally. Experimental data correlate extremely well with design analysis predictions based upon a beam model for the global properties of camber compliance and spanwise bending compliance. Local strain measurements exhibit trends in agreement with intuition and theory but depart slightly from theoretical perfection based upon beam-like behavior alone. It is conjectured that some additional refinement of experimental technique is needed to explain or eliminate these (minor) departures from asymmetric behavior of upper and lower box cover strains. Overall, a solid basis for the design of box structures based upon the bending method of elastic camber production has been confirmed by the experiments. Author

C-130 ADVANCED TECHNOLOGY CENTER WING BOX CONCEPTUAL DESIGN/COST STUDY
R. S. Whitehead, C. R. Foreman (LTV Aerospace Corp., Dallas, TX.), and K. Silva (Wright Lab., Wright-Patterson AFB, OH.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 401-41 (For primary document see N95-28420 09-24)
(Contract F33657-90-D-0027)
Avail: CASI HC A03/MF A04

A conceptual design was developed by Northrop/LTV for an advanced C-130 Center Wing Box (CWB) which could meet the severe mission requirements of the SOF C-130 aircraft. The goals for the advanced technology CWB relative to the current C-130H CWB were: (1) the same acquisition cost; (2) lower operating support costs; (3) equal or lower weight; (4) a 30,000 hour service life for the SOF mission; and (5) minimum impact on the current maintenance concept. Initially, the structural arrangement, weight, external and internal loads, fatigue spectrum, flutter envelope and design criteria for the SOF C-130 aircraft CWB were developed. An advanced materials assessment was then conducted to determine the suitability of advanced materials for a 1994 production availability and detailed trade studies were performed on candidate CWB conceptual designs. Finally, a life-cycle cost analysis was performed on the advanced CWB. The study results showed that a hybrid composite/metallic CWB could meet the severe SOF design requirements, reduce the CWB weight by 14 pct., and was cost effective relative to an all metal beefed up C-130H CWB. DEVELOPMENT OF COMPOSITE CARRYTHROUGH BULKHEAD
R. J. Ehlen and M. Libeskind (Naval Air Development Center, Warminster, PA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 421-44 (For primary document see N95-28420 09-24)
(Contract N62269-87-C-0216)
Avail: CASI HC A03/MF A04

A structural development program was recently completed in which the weight and fatigue advantages of an all composite major load carrying bulkhead was successfully demonstrated. Fabrication of a full scale article, including static and fatigue testing of the carry-through beam portion verified the producibility, strength and durability of this design, thereby presenting the opportunity for use on aircraft upgrades and new aircraft. A 15% weight saving is achievable and, more importantly, the fatigue problems that normally plague metal bulkheads are virtually eliminated. Derived from text

EFFECTS OF FLOOR LOCATION ON RESPONSE OF COMPOSITE FUSELAGE FRAMES
Huey D. Carden, Lisa E. Jones, and Edwin L. Fasanella (Lockheed Engineering and Sciences Co., Hampton, VA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 443-45 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

Experimental and analytical results are presented which show the effect of floor placement on the structural response and strength of circular fuselage frames constructed of graphite-epoxy composite material. The research was conducted to study the behavior of conventionally designed advanced composite aircraft components. To achieve desired new designs which incorporate improved energy absorption capabilities requires an understanding of how these conventional designs behave under crash type loadings. Data are presented on the static behavior of the composite structure through photographs of the frame specimen, experimental strain distributions, and through analytical data from composite structural models. An understanding of this behavior can aid the dynamist in predicting the crash behavior of these structures and may assist the designer in achieving improved designs for energy absorption and crash behavior of future structures. STRUCTURAL DESIGN OPTIMIZATION WITH SURVIVABILITY DEPENDENT CONSTRAINTS APPLICATION: PRIMARY WING BOX OF A MULTI-ROLE FIGHTER **c05**
Douglas J. Dolvin *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 465-48 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

The superior survivability of a multirole fighter is dependent upon balanced integration of technologies for reduced vulnerability and susceptability. The objective is to develop a methodology for structural design optimization with survivability dependent constraints. The design criteria for optimization will be survivability in a tactical laser environment. The following analyses are studied to establish a dependent design relationship between structural weight and survivability: (1) develop a physically linked global design model of survivability variables; and (2) apply conventional constraints to quantify survivability dependent design. It was not possible to develop an exact approach which would include all aspects of survivability dependent design, therefore guidelines are offered for solving similar problems. Derived from text

RELIABILITY ANALYSIS OF COMPOSITE STRUCTURES
Han-Pin Kan *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 489-50 (For primary document see N95-28420 09-24)
(IRAD Proj. R-1056)
Avail: CASI HC A03/MF A04

A probabilistic static stress analysis methodology has been developed to estimate the reliability of a composite structure. Closed form stress analysis methods are the primary analytical tools used in this methodology. These structural mechanics methods are used to identify independent variables whose variations significantly affect the performance of the structure. Once these variables are identified, scatter in their values is evaluated and statistically characterized. The scatter in applied loads and the structural parameters are then fitted to appropriate probabilistic distribution functions. Numerical integration techniques are applied to compute the structural reliability. The predicted reliability accounts for scatter due to variability in material strength, applied load, fabrication and assembly processes. The influence of structural geometry and mode of failure are also considerations in the evaluation. Example problems are given to illustrate various levels of analytical complexity. Author

UNCERTAINTIES IN OBTAINING HIGH RELIABILITY FROM STRESS-STRENGTH MODELS **c38**
Donald M. Neal, William T. Matthews, and Mark G. Vangel *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 503-52 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

There has been a recent interest in determining high statistical reliability in risk assessment of aircraft components. The potential consequences are identified of incorrectly assuming a particular statistical distribution for stress or strength data used in obtaining the high reliability values. The computation of the reliability is defined as the probability of the strength being greater than the stress over the range of stress values. This method is often referred to as the stress-strength model. A sensitivity analysis was performed involving a comparison of reliability results in order to evaluate the effects of assuming specific statistical distributions. Both known population distributions, and those that differed slightly from the known, were considered. Results showed substantial differences in reliability estimates even for almost nondetectable differences in the assumed distributions. These differences represent a potential problem in using the stress-strength model for high reliability computations, since in practice it is impossible to ever know the exact (population) distribution. An alternative reliability computation procedure is examined involving determination of a lower bound on the reliability values using extreme value distributions. This procedure reduces the possibility of obtaining nonconservative reliability estimates. Results indicated the method can provide conservative bounds when computing high reliability. An alternative reliability computation procedure is examined involving determination of a lower bound on the reliability values using extreme value distributions. PROBABILISTIC DESIGN OF ADVANCED COMPOSITE STRUCTURE
P. M. Gray and M. G. Riskalla *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 523-53 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

Advanced composite technology offers potentials for sizable improvements in many areas: weight savings, maintainability, durability, and reliability. However, there are a number of inhibitors to these improvements. One of the biggest inhibitors is the imposition of traditional metallic approaches to design of composite structure. This is especially detrimental in composites because new materials technology demands new design approaches. Of particular importance are the decisions made regarding structural criteria. Significant changes cannot be implemented without careful consideration and exploration. This new approach is to implement changes on a controlled, verifiable basis. Probabilistic design is the methodology and the process to accomplish this. Its foundation is to base design criteria and objectives on reliability targets instead of arbitrary factors carried over from metallic structural history. The background is discussed of probabilistic design and the results are presented of a side-by-side comparison to generic aircraft structure designed the 'old' way and the 'new'. Activities are also defined that need to be undertaken to evolve available approaches to probabilistic design followed by summary and recommendations. Author

PROBABILISTIC EVALUATION OF FUSELAGE-TYPE COMPOSITE STRUCTURES **c05**
Michael C. Shiao (Sverdrup Technology, Inc., Brook Park, OH.) and Christos C. Chamis *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 535-54 Previously announced as N93-12735 (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

A methodology is developed to computationally simulate the uncertain behavior of composite structures. The uncertain behavior includes buckling loads, natural frequencies, displacements, stress/strain etc., which are the consequences of the random variation (scatter) of the primitive (independent random) variables in the constituent, ply, laminate and structural levels. This methodology is implemented in the IPACS (Integrated Probabilistic Assessment of Composite Structures) computer code. A fuselage-type composite structure is analyzed to demonstrate the code's capability. The probability distribution functions of the buckling loads, natural frequency, displacement, strain and stress are computed. The sensitivity of each primitive (independent random) variable to a given structural response is also identified from the analyses. Derived from text

PROOF TEST METHODOLOGY FOR COMPOSITES
Edward M. Wu and David K. Bell *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 1 Sep. 1992 p 549-56 Sponsored in part by DARPA (For primary document see N95-28420 09-24)
Avail: CASI HC A03/MF A04

The special requirements for proof test of composites are identified based on the underlying failure process of composites. Two proof test methods are developed to eliminate the inevitable weak fiber sites without also causing flaw clustering which weakens the post-proof-test composite. Significant reliability enhancement by these proof test methods has been experimentally demonstrated for composite strength and composite life in tension. This basic proof test methodology is relevant to the certification and acceptance of critical composite structures. It can also be applied to the manufacturing process development to achieve zero-reject for very large composite structures. Derived from text

The Navy has been a strong proponent of composites for aircraft structure. Fleet use of composites started with the F-14 in the early 1970's and has steadily increased. This experience base provides sufficient information to allow an evaluation of the maintenance performance of polymer composites in service. A summary is presented of the Navy's experience with maintenance of composite structure. The general types of damage experienced in the fleet as well as specific examples of composite damage to aircraft is described. The impact of future designs on supportability is also discussed. OVERVIEW OF THE ACT PROGRAM

John G. Davis, Jr. *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 577-59 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

NASA's Advanced Composites Program (ACT) was initiated in 1988. A National Research Announcement was issued to solicit innovative ideas that could significantly contribute to development and demonstration of an integrated technology data base and confidence level that permits cost-effective use of composite primary structures in transport aircraft. Fifteen contracts were awarded by the Spring of 1989 and the participants include commercial and military airframe manufacturers, materials developers and suppliers, universities, and government laboratories. The program approach is to develop materials, structural mechanics methodology, design concepts, and fabrication procedures that offer the potential to make composite structures cost-effective compared to aluminum structure. Goals for the ACT program included 30-50 percent weight reduction, 20-25 percent acquisition cost reduction, and provided the scientific basis for predicting materials and structures performance. This paper provides an overview of the ACT program status, plans, and selected technical accomplishments. Sixteen additional papers, which provide more detailed information on the research and development accomplishments, are contained in this publication. Author

DESIGNERS' UNIFIED COST MODEL

W. Freeman, L. Ilcewicz (Boeing Commercial Airplane Co., Seattle, WA.), G. Swanson (Boeing Commercial Airplane Co., Seattle, WA.), and T. Gutowski (Massachusetts Inst. of Tech., Cambridge, MA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 601-61 Previously announced as X92-10406 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The Structures Technology Program Office (STPO) at NASA LaRC has initiated development of a conceptual and preliminary designers' cost prediction model. The model will provide a technically sound method for evaluating the relative cost of different composite structural designs, fabrication processes, and assembly methods that can be compared to equivalent metallic parts or assemblies. The feasibility of developing cost prediction software in a modular form for interfacing with state-of-the-art preliminary design tools and computer aided design programs is being evaluated. The goal of this task is to establish theoretical cost functions that relate geometric design features to summed material cost and labor content in terms of process mechanics and physics. The output of the designers' present analytical tools will be input for the designers' cost prediction model to provide the designer with a database and deterministic cost methodology that allows one to trade and synthesize designs with both cost and weight as objective functions for optimization. This paper presents the team members, approach, goals, plans, and progress to date for development of COSTADE (Cost Optimization Software for Transport Aircraft Design Evaluation). Author

COINS: A COMPOSITES INFORMATION DATABASE SYSTEM c82

Shahid Siddiqi, Louis F. Vosteen, Ralph Edlow, and Teck-Seng Kwa *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 621-62 Previously announced as X92-10407 (For primary document see N95-28462 09-24)
Avail: CASI HC A02/MF A04

An automated data abstraction form (ADAF) was developed to collect information on advanced fabrication processes and their related costs. The information will be collected for all components being fabricated as part of the ACT program and include in a COmposites INformation System (COINS) database. The aim of the COINS development effort is to provide future airframe preliminary design and fabrication teams with a tool through which production cost can become a deterministic variable in the design optimization process. The effort was initiated by the Structures Technology Program Office (STPO) of the NASA LaRC to implement the recommendations of a working group comprised of representatives from the commercial airframe companies. The principal working group recommendation was to re-institute collection of composite part fabrication data in a format similar to the DOD/NASA Structural Composites Fabrication Guide. The fabrication information collection form was automated with current user friendly computer technology. This work in progress paper describes the new automated form and features that make the form easy to use by an aircraft structural design-manufacturing team. Author

COMPOSITE FUSELAGE SHELL STRUCTURES RESEARCH AT NASA LANGLEY RESEARCH CENTER

James H. Starnes, Jr. and Mark J. Shuart *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 631-65 Previously announced as X92-10408 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

Fuselage structures for transport aircraft represent a significant percentage of both the weight and the cost of these aircraft primary structures. Composite materials offer the potential for reducing both the weight and the cost of transport fuselage structures, but only limited studies of the response and failure of composite fuselage structures have been conducted for transport aircraft. The behavior of these important primary structures must be understood, and the structural mechanics methodology for analyzing and designing these complex stiffened shell structures must be validated in the laboratory. The effects of local gradients and discontinuities on fuselage shell behavior and the effects of local damage on pressure containment must be thoroughly understood before composite fuselage structures can be used for commercial aircraft. This paper describes the research being conducted and planned at NASA LaRC to help understand the critical behavior or composite fuselage structures and to validate the structural mechanics methodology being developed for stiffened composite fuselage shell structure subjected to combined internal pressure and mechanical loads. Stiffened shell and curved stiffened panel designs are currently being developed and analyzed, and these designs will be fabricated and then tested at Langley to study critical fuselage shell behavior and to validate structural analysis and design methodology. The research includes studies of the effects of combined internal pressure and mechanical loads on nonlinear stiffened panel and shell behavior, the effects of cutouts and other gradient-producing discontinuities on composite shell response, and the effects of local damage on pressure containment and residual strength. Scaling laws are being developed that relate full-scale and subscale behavior of composite fuselage shells. Failure mechanisms are being identified and advanced designs will be developed based on what is learned from early results from the LaRC research activities. Results from combined load tests will be used to validate analytical models of critical nonlinear response mechanisms as well as shell scaling laws. Author

STRUCTURAL TESTING OF THE TECHNOLOGY INTEGRATION BOX BEAM c39

C. F. Griffin *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 659-67 Previously announced as X92-10409 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

A full-scale section of a transport aircraft wing box was designed, analyzed, fabricated, and tested. The wing box section, which was called the technology integration box beam, contained blade stiffened covers and T-stiffened channel spars constructed using graphite/epoxy materials. Covers, spars, and the aluminum ribs were assembled using mechanical fasteners. The box beam was statically tested for several loading conditions to verify the stiffness and strength characteristics of the composite wing design. Failure of the box beam occurred at 125 percent of design limit load during the combined upbending and torsion ultimate design load test. It appears that the failure initiated at a stiffener runout location in the upper cover which resulted in rupture of the upper cover and portions of both spars. Author

Wang (Lockheed Aeronautical Systems Co., Marietta, GA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 673-68 Previously announced as X92-10410 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The objective of this paper is to describe current results from an on-going study of the mechanisms that led to the failure of the TIBB. Experimental and analytical results are presented. Experimental results include load, strain, and deflection data for the TIBB (Technology Integration Box Beam). An analytical investigation was conducted to compliment the experimental investigation and to gain additional insight into the TIBB structural response. Analytical results include strain and deflection results from a global analysis of the TIBB. A local analysis of the failure region is being completed. These analytical results are validated through comparisons with the experimental results from the TIBB tests. The experimental and analytical results from the TIBB tests are used to determine a sequence of events that may have resulted in failure of the TIBB. A potential cause of failure is high stresses in a stiffener runout region. Typical analytical results are presented for a stiffener runout specimen that is being defined to simulate the TIBB failure mechanisms. The results of this study are anticipated to provide better understanding of potential failure mechanisms in composite aircraft structures, to lead to future design improvements, and to identify needed analytical tools for design and analysis.

DEVELOPMENT OF STITCHED/RTM COMPOSITE PRIMARY STRUCTURES
Susan M. Kullerd (Lockheed Engineering and Sciences Co., Hampton, VA.) and Marvin B. Dow *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 689-71 Previously announced as X92-10411 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The goal of the NASA Advanced Composites Technology (ACT) Program is to provide the technology required to gain the full benefit of weight savings and performance offered by composite primary structures. Achieving the goal is dependent on developing composite materials and structures which are damage tolerant and economical to manufacture. Researchers at NASA LaRC and Douglas Aircraft Company are investigating stitching reinforcement combined with resin transfer molding (RTM) to create structures meeting the ACT program goals. The Douglas work is being performed under a NASA contract entitled Innovative Composites Aircraft Primary Structures (ICAPS). The research is aimed at materials, processes and structural concepts for application in both transport wings and fuselages. Empirical guidelines are being established for stitching reinforcement in primary structures. New data are presented in this paper for evaluation tests of thick (90-ply) and thin (16-ply) stitched laminates, and from selection tests of RTM composite resins. Tension strength, compression strength and post-impact compression strength data are reported. Elements of a NASA LaRC program to expand the science base for stitched/RTM composites are discussed.

Avail: CASI HC A03/MF A04

Automated tow placement (ATP) and stitching of dry textile composite preforms followed by resin transfer molding (RTM) are being investigated by researchers at NASA LaRC and Douglas Aircraft Company as cost-effective manufacturing processes for obtaining damage tolerant fuselage and wing structures for transport aircraft. The Douglas work is being performed under a NASA contract entitled 'Innovative Composites Aircraft Primary Structures (ICAPS)'. Data are presented in this paper to assess the damage tolerance of ATP and RTM fuselage elements with stitched-on stiffeners from compression tests of impacted three-J-stiffened panels and from stiffener pull-off tests. Data are also presented to assess the damage tolerance of RTM wing elements which had stitched skin and stiffeners from impacted single stiffener and three blade-stiffened compression tests and stiffener pull-off tests.

Avail: CASI HC A03/MF A04

Transport fuselage structures are designed to contain pressure following a large penetrating damage event. Applications of composites to fuselage structures require a database and supporting analysis on tension damage tolerance. Tests with 430 fracture specimens were used to accomplish the following: (1) identify critical material and laminate variables affecting notch sensitivity; (2) evaluate composite failure criteria; and (3) recommend a screening test method. Variables studied included fiber type, matrix toughness, lamination manufacturing process, and intraply hybridization. The laminates found to have the lowest notch sensitivity were manufactured using automated tow placement. This suggests a possible relationship between the stress distribution and repeatable levels of material inhomogeneity that are larger than found in traditional tape laminates. Laminates with the highest notch sensitivity consisted of toughened matrix materials that were resistant to a splitting phenomena that reduces stress concentrations in major load bearing plies. Parameters for conventional fracture criteria were found to increase with crack length for the smallest notch sizes studied. Most material and laminate combinations followed less than a square root singularity for the largest crack sizes studied. Specimen geometry, notch type, and notch size were evaluated in developing a screening test procedure. Traitional methods of correcting for specimen finite width were found to be lacking. Results indicate that a range of notch sizes must be tested to determine notch sensitivity. Data for a single small notch size (0.25 in. diameter) was found to give no indication of the sensitivity of a particular material and laminate layup to larger notch sizes.

INDENTABILITY OF CONVENTIONAL AND NEGATIVE POISSON'S RATIO FOAMS
R. S. Lakes and K. Elms *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 789-79 Previously announced as X92-10415 (For primary document see N95-28462 09-24)
Avail: CASI HC A01/MF A04

The indentation resistance of foams, both of conventional structure and of re-entrant structure giving rise to negative Poisson's ratio, is studied using holographic interferometry. In holographic indentation tests, re-entrant foams had higher yield strengths sigma(sub y) and lower stiffness E than conventional foams of the same original relative density. Calculated energy absorption for dynamic impact is considerably higher for re-entrant foam than conventional foam.

LOCAL DESIGN OPTIMIZATION FOR COMPOSITE TRANSPORT FUSELAGE CROWN PANELS c05
G. D. Swanson, L. B. Ilcewicz, T. H. Walker, D. Graesser (Washington Univ., Seattle, WA.), M. Tuttle (Washington Univ., Seattle, WA.), and Z. Zabinsky (Washington Univ., Seattle, WA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep.

1992 p 795-81 Previously announced as X92-10416 (For primary document see N95-28462 09-24)
(Contract NAS1-18889)
Avail: CASI HC A03/MF A04

Composite transport fuselage crown panel design and manufacturing plans were optimized to have projected cost and weight savings of 18 percent and 45 percent, respectively. These savings are close to those quoted as overall NASA ACT program goals. Three local optimization tasks were found to influence the cost and weight of fuselage crown panels. This paper summarizes the effect of each task and describes in detail the task associated with a design cost model. Studies were performed to evaluate the relationship between manufacturing cost and design details. A design tool was developed to aid in these investigations. The development of the design tool included combining cost and performance constraints with a random search optimization algorithm. The resulting software was used in a series of optimization studies that evaluated the sensitivity of design variables, guidelines, criteria, and material selection on cost. The effect of blending adjacent design points in a full scale panel subjected to changing load distributions and local variations was shown to be important. Technical issues and directions for future work were identified. Author

(Contract NAS1-18889)
Avail: CASI HC A03/MF A04

Commercial fuselage structures contain significant challenges in attempting to save manufacturing costs with advanced composite technology. Assembly issues, material costs, and fabrication of elements with complex geometry are each expected to drive the cost of composite fuselage structures. Boeing's efforts under the NASA ACT program have pursued key technologies for low-cost, large crown panel fabrication. An intricate bond panel design and manufacturing concepts were selected based on the efforts of the Design Build Team (DBT). The manufacturing processes selected for the intricate bond design include multiple large panel fabrication with the Advanced Tow Placement (ATP) process, innovative cure tooling concepts, resin transfer molding of long fuselage frames, and utilization of low-cost material forms. The process optimization for final design/manufacturing configuration included factory simulations and hardware demonstrations. These efforts and other optimization tasks were instrumental in reducing cost by 18 percent and weight by 45 percent relative to an aluminum baseline. The qualitative and quantitative results of the manufacturing demonstrations were used to assess manufacturing risks and technology readiness. Author

RECENT PROGRESS IN NASA LANGLEY TEXTILE REINFORCED COMPOSITES PROGRAM
H. Benson Dexter, Charles E. Harris, and Norman J. Johnston *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 845-87 Previously announced as X92-10418 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The NASA LaRC is conducting and sponsoring research to explore the benefits of textile reinforced composites for civil transport aircraft primary structures. The objective of this program is to develop and demonstrate the potential of affordable textile reinforced composite materials to meet design properties and damage tolerance requirements of advanced aircraft structural concepts. In addition to in-house research, the program was recently expanded to include major participation by the aircraft industry and aerospace textile companies. The major program elements include development of textile preforms, processing science, mechanics of materials, experimental characterization of materials, and development and evaluation of textile reinforced composite structural elements and subcomponents. The NASA Langley in-house focus is as follows: development of a science-based understanding of resin transfer molding (RTM), development of powder-coated towpreg processes, analysis methodology, and development of a performance database on textile reinforced composites. The focus of the textile industry participation is on development of multidirectional, damage-tolerant preforms, and the aircraft industry participation is in the areas of design, fabrication and testing of textile reinforced composite structural elements and subcomponents. Textile processes such as 3D weaving, 2D and 3D braiding, and knitting/stitching are being compared with conventional laminated tape processes for improved damage tolerance. Through-the-thickness reinforcements offer significant damage tolerance improvements. However, these gains must be weighed against potential loss in in-plane properties such as strength and stiffness. Analytical trade studies are underway to establish design guidelines for the application of textile material forms to meet specific loading requirements. Fabrication and testing of large structural components are required to establish the full potential of textile reinforced composite materials. Author

COMPARISON OF RESIN FILM INFUSION, RESIN TRANSFER MOLDING, AND CONSOLIDATION OF TEXTILE PREFORMS FOR PRIMARY AIRCRAFT STRUCTURE
J. Suarez and S. Dastin *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 903-93 Previously announced as X92-10420 Sponsored by NASA. Langley Research Center (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

Under NASA's Novel Composites for Wing and Fuselage Applications (NCWFA) Program, Grumman is developing innovative design concepts and cost-effective fabrication processes for damage-tolerant primary structures that can perform at a design ultimate strain level of 6000 micro-inch/inch. Attention has focused on the use of textile high-performance fiber-reinforcement concepts that provide improved damage tolerance and out-of-plane load capability, low-cost resin film infusion (RFI) and resin transfer molding (RTM) processes, and thermoplastic forming concepts. The fabrication of wing 'Y' spars by four different materials/processes methods is described: 'Y' spars fabricated using IM7 angle interlock 0/90 deg woven preforms with +/- 45 deg plies stitched with Toray high-strength graphite thread and processed using RFI and 3501-6 epoxy; 'Y' spars fabricated using G40-800 knitted/stitched preforms and processed using RFI and 3501-6 epoxy; 'Y' spars fabricated using G40-800 knitted/stitched preforms and processed using RTM and Tactix 123/H41 epoxy; and 'Y' spars fabricated using AS4(6k)/PEEK 150-g commingled angle interlock 0/90 deg woven preforms with +/- 45 deg commingled plies stitched using high-strength graphite thread and processed by consolidation. A comparison of the structural efficiency, processability, and projected acquisition cost of these representative spars is presented. Author

(Contract NAS1-18889)
Avail: CASI HC A03/MF A04

Braided composite materials, one of the advanced material forms which is under investigation in Boeing's ATCAS program, have been recognized as a potential cost-effective material form for fuselage structural elements. Consequently, there is a strong need for more knowledge in the design, manufacture, test, and analysis of textile structural composites. The overall objective of this work is to advance braided composite technology towards applications to a large commercial transport fuselage. This paper summarizes the mechanics of materials and manufacturing demonstration results which have been obtained in order to acquire an understanding of how braided composites can be applied to a commercial fuselage. Textile composites consisting of 1D, 2D triaxial, and 3D braid patterns with thermoplastic and two RTM resin systems were investigated. The structural performance of braided composites was evaluated through an extensive mechanical test program. Analytical methods were also developed and applied to predict the following: internal fiber architectures, stiffnesses, fiber stresses, failure mechanisms, notch effects, and the entire history of failure of the braided composites specimens. The applicability of braided composites to a commercial transport fuselage was further assessed through a manufacturing demonstration. Three foot fuselage circumferential hoop frames were manufactured to demonstrate the feasibility of consistently producing high quality braided/RTM composite primary structures. The manufacturing issues (tooling requirements, processing requirements, and process/quality control) addressed during the demonstration are summarized. The manufacturing demonstration in conjunction with the mechanical test results and developed analytical methods increased the confidence in the ATCAS approach to the design, manufacture, test, and analysis of braided composites. THE USE OF IMPACT FORCE AS A SCALE PARAMETER FOR THE IMPACT RESPONSE OF COMPOSITE LAMINATES

Wade C. Jackson (Army Aerostructures Directorate, Hampton, VA.) and C. C. Poe, Jr. *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 981-99
Previously announced as N92-17007 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The building block approach is currently used to design composite structures. With this approach, the data from coupon tests are scaled up to determine the design of a structure. Current standard impact tests and methods of relating test data to other structures are not generally understood and are often used improperly. A methodology is outlined for using impact force as a scale parameter for delamination damage for impacts of simple plates. Dynamic analyses were used to define ranges of plate parameters and impact parameters where quasi-static analyses are valid. These ranges include most low-velocity impacts where the mass of the impacter is large, and the size of the specimen is small. For large-mass impacts of moderately thick (0.35-0.70 cm) laminates, the maximum extent of delamination damage increased with increasing impact force and decreasing specimen thickness. For large-mass impact tests at a given kinetic energy, impact force and hence delamination size depends on specimen size, specimen thickness, boundary conditions, and indenter size and shape. If damage is reported in terms of impact force instead of kinetic energy, large-mass test results can be applied directly to other plates of the same thickness. Author

APPLICATION OF DAMAGE TOLERANCE METHODOLOGY IN CERTIFICATION OF THE PIAGGIO P-180 AVANTI c05

Jerry Johnson *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 999-1012
(For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The Piaggio P-180 Avanti, a twin pusher-prop engine nine-passenger business aircraft was certified in 1990, to the requirements of FAR Part 23 and Associated Special Conditions for Composite Structure. Certification included the application of a damage tolerant methodology to the design of the composite forward wing and empennage (vertical fin, horizontal stabilizer, tailcone, and rudder) structure. This methodology included an extensive analytical evaluation coupled with sub-component and full-scale testing of the structure. The work from the Damage Tolerance Analysis Assessment was incorporated into the full-scale testing. Damage representing hazards such as dropped tools, ground equipment, handling, and runway debris, was applied to the test articles. Additional substantiation included allowing manufacturing discrepancies to exist unrepaired on the full-scale articles and simulated bondline failures in critical elements. The importance of full-scale testing in the critical environmental conditions and the application of critical damage are addressed. The implication of damage tolerance on static and fatigue testing is discussed. Good correlation between finite element solutions and experimental test data was observed. Author

EFFECT OF LOW-SPEED IMPACT DAMAGE AND DAMAGE LOCATION ON BEHAVIOR OF COMPOSITE PANELS

Dawn Jegley *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 1013-1036
Previously announced as N92-23981 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

An investigation of the effects of low-speed impact damage on the compression and tension strength of thin (less than .05 inches thick) and moderately thick (between .12 and .17 inches thick) composite specimens was conducted. Impact speeds ranged from 50 to 550 ft/sec (impact energies from .25 to 30.7 ft-lb) and impact locations were near or away from a lateral unloaded edge. In this study, thin tension-loaded or compression-loaded specimens with only 90 deg and +/- 40 deg plies which were impacted away from the unloaded edge suffered less reduction in maximum load-carrying capability due to impact damage than the same specimens impacted near the unloaded edge. Unlike the thin laminates, failure loads of thicker compression-loaded specimens with a similar stacking sequence were independent of impact location. Failure loads of thin tension-loaded specimens with 0 deg plies were independent of impact location while failure loads of thicker compression-loaded specimens with 0 deg plies were dependent upon impact location. A finite-element analysis of strain distributions across the panel width indicated that high axial strains occur near the unloaded edges of postbuckled panels, indicating that impacts near the unloaded edge would significantly effect the behavior of postbuckled panels. IMPACT DAMAGE RESISTANCE OF COMPOSITE FUSELAGE STRUCTURE, PART 1 c05

E. F. Dost, W. B. Avery, L. B. Ilcewicz, D. H. Grande, and B. R. Coxon (Integrated Technologies, Inc., Bothell, WA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 1037-1069 (For primary document see N95-28462 09-24)
(Contract NAS1-18889)
Avail: CASI HC A03/MF A04

The impact damage resistance of laminated composite transport aircraft fuselage structures was studied experimentally. A statistically based designed experiment was used to examine numerous material, laminate, structural, and extrinsic (e.g., impactor type) variables. The relative importance and quantitative measure of the effect of each variable and variable interactions on responses including impactor dynamic response, visibility, and internal damage state were determined. The study utilized 32 three-stiffener panels, each with a unique combination of material type, material forms, and structural geometry. Two manufacturing techniques, tow placement and tape lamination, were used to build panels representative of potential fuselage crown, keel, and lower side-panel designs. Various combinations of impactor variables representing various foreign-object-impact threats to the aircraft were examined. Impacts performed at different structural locations within each panel (e.g., skin midbay, stiffener attaching flange, etc.) were considered separate parallel experiments. The relationship between input variables, measured damage states, and structural response to this damage are presented including recommendations for materials and impact test methods for fuselage structure. Objectives of customer mandated aircraft structural integrity initiatives in design are to guide material selection, to incorporate fracture resistant concepts in the design, to utilize damage tolerance based allowables and planned inspection procedures necessary to enhance the safety and reliability of manned flight vehicles. However, validated fracture analysis tools for composite structures are needed to accomplish these objectives in a timely and economical manner. This paper briefly describes the development, validation, and application of a damage tolerance methodology for composite airframe structures. A closed-form analysis code, entitled SUBLAM was developed to predict the critical biaxial strain state necessary to cause sublaminate buckling-induced delamination extension in an impact damaged composite laminate. An embedded elliptical delamination separating a thin sublaminate from a thick parent laminate is modelled. Predicted failure strains were correlated against a variety of experimental data that included results from compression after impact coupon and element tests. An integrated analysis package was developed to predict damage tolerance based margin-of-safety (MS) using NASTRAN generated loads and element information. Damage tolerance aspects of new concepts are quickly and cost-effectively determined without the need for excessive testing. Author

Avail: CASI HC A03/MF A04

Tests were performed assessing the effectiveness of repair in restoring the mechanical properties of damaged, solid composite plates made of Fiberite T300/976 graphite-epoxy. Some (75%) or all (100%) of the damaged zone was cut out, and the plate was repaired by plugging and patching the hole. The effectiveness of the repair was evaluated by measuring the compressive strengths of undamaged plates, damaged plates with no cutout, damaged plates with a cutout, and plates that had been repaired. POST IMPACT COMPRESSIVE STRENGTH IN COMPOSITES

c39

Edvins Demuts, Raghbir S. Sandhu, and John A. Daniels *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 1097-1104 (For primary document see N95-28462 09-24)
Avail: CASI HC A02/MF A04

Presented in this paper are the plan, equipment, procedures, and findings of an experimental investigation of the tolerance to low velocity impact of a graphite epoxy (AS4/3501-6) and graphite bismaleimide (M6/CYCOM3100) advanced composites. The applied impacts were governed by the Air Force Guide Specification 87221. Specimens of each material system having a common nominal layup (10% 0 deg; 80% +/-45 deg; 10% 90 deg), a common 7 inch (17.78 cm) by 10 inch (25.40 cm) size, five different thicknesses (9, 26, 48, 74, and 96 plies), and ambient moisture content were impacted and strength tested at room temperature. Damaged areas and post impact compression strengths (PICS) were among the most significant findings obtained. While the undamaged per ply compression strength of both materials is a strong function of laminate thickness, the per ply PICS is not. The average difference in per ply PICS between the two material systems is about seven percent. Although a smaller percentage of the applied kinetic energy was absorbed by the Gr/BMI than by the Gr/Epoxy composites, larger damaged areas were produced in the Gr/BMI than in Gr/Epoxy. Within the limitations of this investigation, the Gr/BMI system seems to offer no advantage in damage tolerance over the Gr/Epoxy system examined. Derived from text

FUNDAMENTAL CONCEPTS IN THE SUPPRESSION OF DELAMINATION BUCKLING BY STITCHING

B. N. Cox *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 1105-1110 (For primary document see N95-28462 09-24)
Avail: CASI HC A02/MF A04

Elementary results are presented for the buckling of stitched, laminated composites containing delamination cracks. The stitching fibers are assumed to provide continuous, linear restoring tractions opposing the deflection of the delaminated layer adjacent to the crack. It is shown that there exists a characteristic length a(0) for buckling: if the length, 2a, of the delamination crack exceeds 2a(0), then, when buckling occurs, it will consist of waves of period 2a(0) and will usually not span the whole delamination. Simple expressions are derived for the critical buckling load and the minimum stitching density required to suppress buckling of the delaminated layer. Author

DAMAGE TOLERANCE OF A GEODESICALLY STIFFENED ADVANCED COMPOSITE STRUCTURAL CONCEPT FOR AIRCRAFT STRUCTURAL APPLICATIONS

c05

Marshall Rouse and Damodar R. Ambur *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 1111-1121 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

This paper describes the features of a geodesically stiffened panel concept that was designed for a fuselage application with a combined axial compression loading of 3,000 lb/in. and a shear loading of 600 lb/in. Specimens representative of this panel concept were tested in uniaxial compression both with and without low-speed impact damage to study the buckling and postbuckling response of the structure. Experimental results that describe the stiffness and failure characteristics of undamaged and impacted damage specimens are presented. A finite element analysis model that captures the principal details of the specimens was developed and used to predict the panel response. Analytical results on panel end-shortening are compared with the experimental results. Analytical results that describe panel end-shortening, out-of-plane displacement and stress resultants are presented. Derived from text

ADVANCED WING DESIGN SURVIVABILITY TESTING AND RESULTS

c05

J. Bruno and M. Tobias (Naval Air Development Center, Warminster, PA.) *In* FAA, Ninth DOD/NASA/FAA Conference on Fibro us Composites in Structural Design, Volume 2 Sep. 1992 p 1123-1137 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

Composite wings on current operational aircraft are conservatively designed to account for stress/strain concentrations, and to assure specified damage tolerance. The technology that can lead to improved composite wing structures and associated structural efficiency is to increase design ultimate strain levels beyond their current limit of 3500 to 4000 micro-in/in to 6000 micro-in/in without sacrificing structural integrity, durability, damage tolerance, or survivability. Grumman, under the sponsorship of the Naval Air Development Center (NADC), has developed a high-strain composite wing design for a subsonic aircraft wing using novel and innovative design concepts and manufacturing methods, while maintaining a state-of-the-art fiber/resin system. The current advanced wing design effort addressed a tactical subsonic aircraft wing using previously developed, high-strain wing design concepts in conjunction with newer/emerging fiber and polymer matrix composite (PMC) materials to achieve the same goals, while reducing complexity. Two categories of advanced PMC materials were evaluated: toughened thermosets; and engineered thermoplastics. Advanced PMC materials offer the technological opportunity to take maximum advantage of improved material properties, physical characteristics, and tailorability to increase performance and survivability over current composite structure. Damage tolerance and survivability to various threats, in addition to structural integrity and durability, were key technical issues addressed during this study, and evaluated through test. This paper focuses on the live-fire testing, and the results performed to experimentally evaluate the survivability of the advanced wing design. Derived from text

NASA-ACEE/BOEING 737 GRAPHITE-EPOXY HORIZONTAL STABILIZER SERVICE **c05**

J. T. Quinlivan, J. A. Kent, and D. R. Wilson *In* FAA, Ninth DOD/NASA/FAA Conference on Fibrous Composites in Structural Design, Volume 2 Sep. 1992 p 1139-1150 (For primary document see N95-28462 09-24)
Avail: CASI HC A03/MF A04

The 737 graphite-epoxy horizontal stabilizer was developed by Boeing as part of the NASA-ACEE (Aircraft Energy Efficiency) Advanced Composite Structures Program. NASA-ACEE programs challenged large-transport manufacturers to use graphite material in redesigning existing aircraft components. The goal of the program was to develop the necessary data and technology to achieve production commitments to advanced composites. Boeing designed, fabricated, and certified five shipsets of horizontal stabilizers for the 737-200 airframe. The program was initiated in July 1977 and certification was achieved in August 1982. Schedule highlights are shown. The work performed on this program is reported in NASA technical summaries and final reports. Boeing introduced the stabilizer into commercial operation in 1984, and has maintained surveillance for seven years of in-service evaluation. Outstanding performance was demonstrated with no service incidents attributed to the graphite-epoxy structure. Boeing will continue to monitor and support these aircraft, adding to the database of commercial composite experience. Derived from text

NON-LINEAR VISCOELASTIC BEHAVIOUR

A. D. Irving, S. J. Watson, L. J. J. Speet, N. Cunliffe, and T. Dewson Dec. 1994 27 p Prepared in cooperation with Technische Univ.
(PB95-192811; RAL-94-123) Avail: Issuing Activity (National Technical Information Service (NTIS))

This paper is concerned with the development of a quantitative analysis method that can extract the mixed linear and non-linear dynamical response of a viscoelastic process in composite materials. A tractable set of simultaneous equations with well behaved coefficients can be generated by taking time series moments of a suitably truncated Volterra series expansion. This moment hierarchy is a set of inhomogeneous non-linear integral equations, based on a vector multidimensional convolution form of the Volterra functional series expansion. The hierarchy developed is used to analyze the time dependent viscoelastic properties of fiber reinforced composite materials. Estimates of the temporal response of the measured stress to the measured mechanical force were then used to predict the out of sample stress field values. It is demonstrated that the response functions provided a good representation of the viscoelastic process. Generally speaking, the response functions estimated from the data are used to determine the dynamic and steady state transport coefficients, which can be used to develop either an empirical field theory of the phenomena or alternatively be used in the design process. The performance of ramjets burning slurry fuels (leading to condensed oxide aerosols and liquid film deposits), gas turbine engines in dusty or marine atmospheres, or when using fuels from non-traditional sources, depends upon the formation and transport of small particles across non-isothermal combustion gas boundary layers (BLs). Even airbreathing engines burning 'clean' hydrocarbon fuels can experience soot formation/deposition problems (e.g., combustor liner burnout, accelerated turbine blade erosion and 'hot' corrosion). Moreover, particle formation and transport are important in many chemical reactors used to synthesize or process aerospace materials (turbine blade coatings, optical waveguides, ceramic precursor powders, fibers for composites,...) Accordingly, our research is directed toward providing chemical propulsion systems engineers and materials- oriented engineers with new techniques and quantitative information on important particle- and vapor-mass transport mechanisms and rates. The purpose of this report is to summarize our research methods accomplishments. DTIC

A BOOK AND SERIES OF MONOGRAPHS ON ICE PHYSICS Final Report, 1 Jun. 1991 - 31 May 1994
Victor F. Petrenko 22 Aug. 1994 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0164)
(AD-A288319; ARO-28599.4-GS) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

During the period June 1, 1991, through May 31, 1994 five monographs on the physics of ice were written and printed: (1) the structure of ordinary ice. part 1: ideal structure of ice; (2) defects in ice. part 1: point defects; (3) defects in ice. part 2: dislocations and plane defects; (4) electrical properties of ice: part 1. conductivity and dielectric permittivity of ice. part 2. advanced topics and new physical phenomena; and (5) the surface of ice. These monograph number 456 pages including 145 figures and 510 references. The lists of the monographs in contents is in the Appendix. The first five monographs of the series passed through intensive review and were very well accepted by scientists and engineers working on ice. The sixth monograph entitled electromechanical effects in ice is written and is being reviewed. DTIC

FREZCHEM: A CHEMICAL-THERMODYNAMIC MODEL FOR AQUEOUS SOLUTIONS AT SUBZERO TEMPERATURES
Giles M. Marion and Steven A. Grant Jul. 1994 40 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288456; CRREL-SR-94-18) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report documents a FORTRAN version of the Spencer-Moller-Weare chemical thermodynamic model for aqueous electrolyte solutions at sub-zero temperatures (FREZCHEM). FREZCHEM is structured to predict the chemical composition and unfrozen water of aqueous solutions between -60 and +25 C at atmospheric pressure (0.101325 MPa). FREZCHEM includes two reaction pathways: freezing at variable temperature and fixed total water and evaporation at variable water and fixed temperature. Activity coefficients and the activity of water are calculated using the Pitzer equations, which are valid to high solution ionic strengths (approximately 20 mol/kg). Fifteen chloride and sulfate salts of sodium, potassium, calcium, and magnesium are included in the model. Predicted and experimental measurements of solute molalities and the unfrozen water fraction during sea water freezing are in good agreement. At -50 C, 0.3% of sea water remains unfrozen with 99.7% of Na and 95.5% of Cl having precipitated into one of four salts. FREZCHEM should find many applications in physicochemical studies of aqueous solutions and freezing. DTIC

CONTINUUM MECHANICAL MODELING OF SOLIDS UNDERGOING A PHASE TRANSFORMATION Final Report, 1 Jan. 1991 - 30 Jun. 1994
Rohan Abeyaratne 25 Aug. 1994 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0011)
(AD-A288274; ARO-227538.12-EG) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report summarizes our research on the continuum mechanical modeling of materials that undergo stress and temperature induced phase transitions. It contains a problem statement, a summary of results, a list of publications, and names of personnel. The results pertain to the construction of the model, the study of the model in both quasi-static and inertial settings, a study of coupled thermomechanical effects, a study of cyclic effects and comparison with experiments. STRUCTURE OF ORDINARY ICE Ih. PART 2: DEFECTS IN ICE. VOLUME 1: POINT DEFECTS
Victor F. Petrenko and Robert W. Whitworth (Birmingham Univ., England.) Apr. 1994 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0164)
(AD-A288279; CRREL-SR-94-4; ARO-28599.3-GS) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report examines point defects in ice: molecular defects (vacancies and interstitials), protonic point defects (ions and Bjerrum defects) and electronic point defects (solvated electrons and radicals). Experimental results and theoretical models of the defects' atomic and electronic structures, energies and mobilities are reviewed. Special attention is given to the results of studies from the last two decades. Among the experimental techniques under consideration are nuclear magnetic resonance, X-rays topography, electron spin resonance, measurements of ice conductivity and dielectric permittivity, spectra of optical absorption and photoluminescence, and measurements of diffusion coefficients of the oxygen and hydrogen isotopes in ice. Ab initio calculations, computer simulations, Jaccard's theory and soliton models are used to discuss the defects' structures and their properties. DTIC

NUMERICAL SIMULATION OF COMBUSTION FLOW AROUND A FLAME HOLDER WITH HYDROGEN INJECTION
Takeshi Yamamoto and Takashi Tamaru Apr. 1994 17 p In JAPANESE Original contains color illustrations
(ISSN 0389-4010)
(NAL-TR-1233) Avail: CASI HC A03/MF A01

In the National Aerospace Laboratory, research work on a hydrogen-fueled ramjet engine for the spaceplane is being carried out. As a part of their research, a bluff-body type flame holder with fuel injection was tested at atmospheric conditions and prospective results were obtained for the engine. However, the capability of the experimental facility was limited, and it was difficult to investigate the engine performance over a wide operating range. so a two-dimensional CFD (Computational Fluid Dynamics) code was developed to simulate engine performance over a wide operating range. The code is based on the SIMPLER algorithm, and the power law scheme is used for the discretization of the governing equations. Turbulence is simulated by Myong-Kasagi's low Reynolds number type k-epsilon model. Magnussen's eddy-dissipation concept is used to simulate the combustion. In this report, details of the CFD code and some typical results of the numerical simulation are described. Author

PHOTO AND THERMAL EXCITATION OF SURFACE CHEMISTRY ON MODEL CATALYST SURFACES Final Report, 1 Sep. 1991 - 31 Aug. 1994
John T. Yates, Jr. 28 Jun. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0323)
(AD-A288541; ARO-29227.16-CH) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This is an overview of 16 publications written in the 36 month period of a contract from ARO. The work falls into three main categories: (1) Oxidation of phosphorus on Mo catalyst surfaces, probing the rate limiting step in the oxidative destruction of organophosphonate compounds. (2) Carbon monoxide and oxygen dissociative chemistry on Mo(110) surfaces, probing the fate of CO and oxygen. CO is an important oxidation product in the catalytic oxidative destruction of organic compounds. (3) Photodesorption and photocatalysis on oxide surfaces. DTIC

FRACTIONATION STUDIES OF POLYETHYLENE USING DSC-TECHNIQUE
P. Starck 18 Oct. 1994 45 p *Its* Polymer Technology Publ. No. 21

(ISSN 0785-7144)
(PB95-185252; ISBN-951-22-2347-3) Avail: CASI HC A03/MF A01

This review will discuss work done on both well characterized LDPE, LLDPE and VLLDPE resins as well as on commercially available 'metallocene' type polyethylenes and corresponding test grades produced at Helsinki University of Technology (HUT) and at Borealis, respectively. The technique applied in this work is a segregation fractionation technique (SFT) by differential scanning calorimetry (DSC). In this technique the polymers studied have been annealed in stages at decreasing temperatures starting from a temperature just above the melting temperature. The results obtained will be compared to earlier obtained Temperature Rising Elution Fractionation (TREF)-data and discussed together with most recent literature in this area. NTIS

APPLICATIONS OF SECOND HARMONIC AND SUM FREQUENCY GENERATION TO GRAPHITE AND SILICA TYPE INTERFACES Final Technical Report, Apr. 1991 - Aug. 1994
E. Borguet, A. N. Tarmovsky, X. Wang, D. Zhang, and K. B. Eisenthal
Aug. 1994 17 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0190-91)
(AD-A288228; AFOSR-94-0695TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Second Harmonic (SHG) and Sum-Frequency Generation (SFG) have enabled the investigation of the physical and chemical properties of aqueous interfaces, yielding new information and considerable insight into the structure and dynamics at a molecular level. Novel behavior has been observed and valuable new methodologies have been developed. IR-Visible SFG has enabled the behavior of distinct chromophores within a molecular species at an aqueous interface to be monitored for the first time. An unexpected phase transition was observed at the liquid/vapor interface of aqueous solutions of acetonitrile. The structural change is manifested by shifts in the vibrational frequency and in the polarization of the SFG signal of the interfacial acetonitrile. This transition is analogous to those observed for monolayers of long chain amphiphilic species, also monitored for the first time with chromophore sensitivity. These results provide direct evidence that head and tail groups of amphiphilic molecules can orient independently, and a challenging picture of the nature of phase transitions in two dimensional molecular assemblies. Electric Field Induced Second Harmonic Generation (EFISHG), a novel probe of charged interfaces, has been developed and applied to the study of the silica/aqueous interface and charged amphiphilic monolayers. Fundamental chemical quantities, such as the pKa of interfacial molecules, have been measured. In general, the interfacial acid-base equilibrium is shifted, with respect to the bulk, in a direction that favors the neutral species. Studies of the acid-base equilibrium of the silica/aqueous interface revealed two silanol sites whose acidity and thermodynamic parameters were determined. DTIC

STABILIZATION AND CONTROL OF HIGH ENERGY INTERMEDIATES THROUGH ADSORPTION OF RESTRICTED SPACES Final Technical Report, 1 Sep. 1991 - 31 Aug. 1994
Nicholas J. Turro 16 Sep. 1994 12 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0340-91; AF Proj. 2303)
(AD-A288552; AFOSR-94-0679TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The research supported by this AFOSR grant has involved a multi-technique (NMR, ESR, laser flash photolysis, single photon counting, photoluminescence, tailor-made syntheses, computer simulation) approach to address problems concerning the structure and dynamics of transient high energy intermediates. These techniques have been employed to investigate the behavior of these intermediates when the latter are confined to the interfacial regions of restricted reaction spaces such as micelles, zeolites, cyclodextrins, water soluble polymers, and silica. Unique information has been obtained concerning the nature of interactions between the transients as substrates bound to receptors by non-covalent bonding. This information, in turn, has been exploited to investigate situations for which the transients display extraordinary dynamic properties such as reactivity which is controlled by the application of very weak applied magnetic fields. RAM ACCELERATOR PERFORMANCE CALCULATIONS USING A MODIFIED VERSION OF THE NASA CET89 EQUILIBRIUM CHEMISTRY CODE Final Report, Sep. 1993 - Mar. 1994
Federico Liberatore Dec. 1994 54 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289554; ARL-TR-687) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The equilibrium chemistry code, CET89, is modified to calculate the performance of ram projectiles using 1-D control volume derived governing equations. The modified program is capable of calculating the projectile thrust and chemical energy release as functions of projectile velocity. This information is then used to calculate the distance versus time trace of a projectile traveling through an accelerator barrel. The modified program retains the full use of the thermodynamic database of the original code thus permitting performance calculations for a wide range of reactant mixtures. DTIC

MEASUREMENT OF VISCOSITY BY CAPILLARY RHEOMETRY: DWELL TIME EFFECTS
C. S. Brown and C. R. G. Allen May 1994 16 p
(PB95-190203; NPL-DMM-(A)-140) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Reliable viscosity data are needed by industry for a number of reasons, as a guide to designing products and choosing appropriate grades of material, to predict how a polymer will flow in commercial processing situations and to provide feedback during processing operations. Capillary rheometry is often used by industry to measure the viscosity of polymers. However, there is uncertainty over how long to leave a sample in the rheometer prior to measuring its viscosity. This has become more of a problem as processing temperatures have been pushed to the limit. The effect of different dwell times on viscosity measurement was examined in the context of the ISO Standard 11443. It was concluded that dwell times of five minutes were insufficient to achieve reliable viscosity measurements, whereas dwell times of thirty minutes were found to be sufficient. No evidence of degradation was observed for dwell times of two hours or less where the testing temperature was within the recommended processing temperature range, however, at higher temperatures a slight (less than 10%) reduction in viscosity was recorded. The unusual behavior of filled polypropylene increasing in viscosity, seen previously in rotational rheometry, was not observed in capillary rheometry. This is in agreement with the explanation proposed previously. This work should enable industry to use capillary rheometry to measure viscosity with more confidence in the future. NTIS

DETERMINING NANOSCALE PHYSICAL PROPERTIES OF MATERIALS BY MICROSCOPY AND SPECTROSCOPY
Mehmet Sarikaya, H. K. Wickramasinghe, and Michael Isaacson 1994 610 p Prepared in cooperation with IBM T. J. Watson Research Center, and Cornell Univ. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-94-1-0076)
(AD-A289532) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

As the capabilities of microscopy techniques to investigate materials at smaller dimensions improve, processing techniques advance in parallel. In fact, materials synthesis with better-controlled spatial variations at a smaller scale has been demonstrated in many areas of materials and biological sciences. The major purpose of this symposium was not only to use microscopy and spectroscopy techniques for imaging, and compositional and chemical analysis of bulk and surface structures, but also to show that these newly emerging techniques are now capable of directly measuring physical and chemical properties of nanostructured biological and synthetic materials at a local scale. The concept of determining nanoscale properties of materials by microscopy and spectroscopy, therefore, can be expected to open up new avenues for science and engineering of materials, as firmly demonstrated by this symposium. Microscopy techniques included those that use photons, x-rays, electrons, and scanning probe techniques at their highest resolutions, all less than 1000 A down to nanometer and molecular levels, and in some cases 1 A and smaller. Similarly, spectroscopy techniques included local measurements of bonding, electronic, optical, and magnetic properties, again using probes at the nanometer scale. All of the invited presentations, and many of the extraordinary contributed papers, represented the latest applications of the techniques at the highest resolution levels. DTIC

PHOTOLUMINESCENCE SPECTROSCOPY OF 4H- AND 6H-SIC M.S. Thesis
William A. Davis Dec. 1994 81 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289326; AFIT/GAP/ENP/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Typical undoped bulk grown SiC shows n- or p-type conductivity due to residual impurities such as nitrogen, boron, or aluminum. In order to produce high resistivity material, vanadium can be used as a compensating dopant. Since vanadium is an amphoteric dopant in SiC, it produces either a donor state, V(sub Si)(4+) (3d sup 1) yields V(sub Si)(5+) (3d sup 0), or an acceptor state, V(sub Si)(4+) (3d sup 1) yields V(sub Si)(3+)(3d sup 2). Thus, vanadium doping can compensate both n- and p-type conductivity. In this work, vanadium doped and undoped 4H- and 6H-SiC grown by the sublimation method have been studied using low temperature photoluminescence (PL). It was found that the luminescence observed between 0.85 to 0.95 eV of the intra-3d-shell transition of V(sub Si)(4+) (3d sup 1) increased by an order of magnitude in samples intentionally doped with vanadium compared to samples unintentionally doped. In addition, the dominant visible-region luminescence was attributed to titanium which is an isoelectronic trap in SiC. The presence of a broad peak centered at approx. 1.90 eV in some samples is believed to be attributed to donor-acceptor pair recombination between a Ti sub Si-N(sub c) complexdonor and the boron defect complex acting as an acceptor. Finally, the Ti sub Si-N(sub c) complex donor location in the bandgap of 6H-SiC is estimated to be E sub c-0.54 eV. DTIC

OPTICAL FEATURES OF NANOSIZE IRON AND MOLYBDENUM SULFIDE CLUSTERS
J. P. Wilcoxon, G. Samara, and P. Newcomer 1995 4 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-005417; SAND-94-3001C; CONF-941144-49) Avail: CASI HC A01/MF A01

In the bulk state FeS2 and MoS2 are optically opaque, narrow bandgap semiconductors with no optical applications. We demonstrate that nanosize FeS2 and MoS2 have bandgaps that can be adjusted to the visible and even UV region of the spectrum by control of the cluster size. This opens up a host of applications of these materials as inexpensive solar photocatalysts. We demonstrate that the band-gap of both materials shifts to the blue with decreasing size but ceases shifting when a size of approximately 3 nm (in the case of MoS2) is attained. We interpret this observation as a change from bulk quantum confinement of the hole-electron pair of a tiny semiconductor to a set of discrete molecular-like transitions more characteristic of a whopper molecule. Room temperature photoemission studies of these clusters demonstrate that, while photoemission shifts to the blue with increasing bandgap for large clusters, small clusters have photoemission exclusively from trapped sub-bandgap surface states. Chemical modification of the surface to introduce hole or electron traps can result in either an enhancement or a decrease in the photoluminescence. In addition, we report our results concerning chemical purification and preliminary surface characterization of MoS2 clusters by chromatography. DOE

MOLECULAR APPROACH TO MESOPOROUS METAL SULFIDES
M. T. Anderson and P. Newcomer 1995 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-005418; SAND-94-1770C; CONF-941144-48) Avail: CASI HC A02/MF A01

We have synthesized metal-sulfide/surfactant nanocomposite materials by cooperative assembly of molecular precursors in a aqueous medium. The template-mediated synthetic approach is applicable to metals sulfides that exhibit aqueous thiometallate chemistry. The products are lamellar and have a bilayers or interdigitated layers of surfactant molecules sandwiched between metal sulfide layers. The layers of anionic metal sulfide molecules are not completely condensed in the nanocomposites, which results in a negative charge on the metal sulfide layers. The materials are stable at room temperature in water, methanol, 1 M HCl, 30 wt% NH3, and 1 M NaOH. The materials do not dissolve at 80 C in water and are stable to at least 180 C in air. The nanocomposites exhibit ion exchange of smaller surfactants, alkali-metal ions, and divalent metal ions. DOE

IRON OXIDES CHARACTERIZATION BY MOESSBAUER SPECTROSCOPY Ph.D. Thesis [CARACTERIZACION DE OXIDOS DE HIERRO POR ESPECTROSCOPIA MOSSBAUER]
R. BasurtoSanchez 1993 58 p In SPANISH
(DE95-607869; INIS-mf-14397) Avail: CASI HC A04/MF A01 (US Sales Only)

In this work rust development on low carbon wire surface after the conformation process at different temperatures was studied by Moessbauer spectroscopy. The characterization was made by determining the following spectral parameters; Quadrupole splitting, Isomer shift, and Magnetic splitting. The area quantification determined the percentage amount of three different iron oxides. These iron oxides were: Wustite (FeO), Hematite (Fe2O3), and Magnetite (Fe3O4) which were present in the rust studied. With the results it was possible to establish the best temperature to favor the development of each of these iron oxides. DOE

HIGH RESOLUTION FOURIER TRANSFORM SPECTROSCOPY OF THE FIRST OVERTONE OF THE N-O STRETCH IN NITROSYL BROMIDE M.S. Thesis
Todd E. Wiest Sep. 1994 117 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289318; AFIT/GAP/ENP/94D-11) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Infrared Fourier transform spectroscopy of the first overtone of the nitric oxide (NO) bond stretch in nitrosyl bromide (ONBr) has been performed at a resolution of 0.02 cm(exp -1) to obtain the rotational parameters of the v(sub 1) = 2 energy level. Roughly 1000 transitions have been observed for rotational levels up to J = 80 and K(sub a) = 7. The calculation of the complete set of rotational energy levels of this asymmetric molecule requires the numerical diagonalization of four tridiagonal matrices for each J. From a nonlinear least squares fit of observed transitions with J less than or equal to 40 using an approximation for the energy levels, the maximum J value accurately approximated was determined to be twenty-four. The fit was reaccomplished for J less than or equal to 24. Monte Carlo analysis suggests the need to use higher J levels to determine the distortion constants. DTIC

THE INFLUENCE OF SURFACE STRUCTURE ON THE INTERACTION OF WATER WITH TIO2(100)
M. A. Henderson Nov. 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC06-76RL-01830)
(DE95-004927; PNL-SA-25472; CONF-941144-30) Avail: CASI HC A02/MF A01

The influence of surface structure on the interaction of water with TiO2(100) (rutile) was investigated. Two unique surface structures of the (100) crystal face can be prepared by oxidation (the bulk-terminated surface) and by vacuum reduction (the (110)- microfaceted surface). Thermal desorption profiles, which measure the strength of the adsorbate-surface interaction, indicate that submonolayer coverages of water are more stable on the bulk-terminated surface than on the (110)-microfaceted surface. Also, subtle differences exist in the way water interacts with 2-coordinate O(sup 2-) sites on these two surfaces. The implications of these results for chemistry on microcrystallines particle are considered. DOE

COMPARISON OF THE ACTIVITIES OF FINE-PARTICLE SIZE CATALYSTS
F. V. Stohl, K. V. Diegert, and D. C. Goodnow 1994 7 p Presented at the 209th American Chemical Society National Meeting, Anaheim, CA, 2-7 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-004773; SAND-94-2917C; CONF-950402-1) Avail: CASI HC A02/MF A01

The objectives of Sandia's fine-particle size catalyst testing project are to evaluate and compare the activities of the fine-particle size catalysts being developed in DOE/PETC's Advanced Research Coal Liquefaction Program by using standard coal liquefaction test procedures. The standard procedures use Blind Canyon coal, phenanthrene as the reaction solvent, and a factorial experimental design with temperatures from 350 C to 400 C, reaction times from 20 to 60 minutes, and catalyst loadings up to 1 wt%. Catalytic activity is measured in terms of tetrahydrofuran conversion, heptane conversion, the amount of 9, 10-dihydrophenanthrene in the product, and the gas yield. Several catalysts have been evaluated including a commercially available pyrite, a sulfated iron oxide from the University of Pittsburgh, and several preparations of 6-line ferrihydrites from Pacific Northwest Laboratories. Results have demonstrated that significant differences in activity can be detected among these catalysts. DOE

THREE-DIMENSIONAL COMPUTER MODELING OF HYDROGEN INJECTION AND COMBUSTION
Norman L. Johnson, Anthony A. Amsden, Jeff D. Naber (Sandia Labs., Livermore, CA.), and Dennis L. Siebers (Sandia Labs., Livermore, CA.) 1995 10 p Presented at the SMS Simulation Multiconference: Simulation As A Critical Technology, Phoenix, AZ, 9-13 Apr. 1995 Sponsored by the Department of Energy Hydrogen Program
(Contract W-7405-eng-36)
(DE95-006261; LA-UR-95-210; CONF-950439-7) Avail: CASI HC A02/MF A01

The hydrodynamics of hydrogen gas injection into a fixed-volume combustion chamber is analyzed and simulated using KIVA-3, a three-dimensional, reactive flow computer code. Comparisons of the simulation results are made to data obtained at the Combustion Research Facility at Sandia National Laboratory-California (SNL-CA). Simulation of the gas injection problem is found to be of comparable difficulty as the liquid fuel injection in diesel engines. The primary challenge is the large change of length scale from the flow of gas in the orifice to the penetration in the combustion chamber. In the current experiments, the change of length scale is about 4,000. A reduction of the full problem is developed that reduces the change in length scale in the simulation to about 400, with a comparable improvement in computational times. Comparisons of the simulation to the experimental data shows good agreement in the penetration history and pressure rise in the combustion chamber. At late times the comparison is sensitive to the method of determination of the penetration in the simulations. In a comparison of the combustion modeling of methane and hydrogen, hydrogen combustion is more difficult to model, and currently available kinetic models fail to predict the observed autoignition delay at these conditions. MEASUREMENTS OF THE VOLATILITIES OF ELECTROLYTES: APPLICATION TO WATER/STEAM CYCLES
D. A. Palmer, J. M. Simonson, and J. P. Jensen (Technical Univ. of Denmark, Lyngby, Denmark.) 1995 13 p Presented at the 4th International Conference on Fossil Plant Cycle Chemistry, Atlanta, GA, 7-9 Sep. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007103; CONF-940982-1) Avail: CASI HC A03/MF A01

This article describes recent results of a laboratory-scale research project aimed at measuring partitioning constants for a range of electrolytes that are known to be present in commercial power-plant boilers and/or are a potential hazard in terms of chemical carry-over of corrosive species to the LP turbines. Particular emphasis has been placed on measurements of NaOH, H2SO4 and the intermediate salts NaHSO4 and Na2SO4. These results indicate that a rapid chemical equilibrium exists with the formation of minor accounts of 'sulfites' at the elevated temperatures investigated, viz. to 350 C 662 F, or ca. 165 bar, or 2400 psi. A computerized model is under development incorporating the partitioning constants of HCl, NH4Cl, NaCl, NaOH, H2SO4, NaHSO4, and NH3, as well as the related hydrolysis constants and the ion product of water with the goal of providing a tool for predicting the composition of steam and condensate formed in the water/steam cycle of power plants with drum boilers. These calculations are by necessity based on equilibrium conditions, but demonstrate the impact of the ratio of amount of condensate formed to steam generated, particularly with respect to the pH of the condensate and the build-up of high concentrations of solutes. Moreover, the most recent calculations indicate the importance of the Na(sup +):anion ratio in the boiler water with regard to the pH of the first condensate. A number of examples of various boiler water compositions have been tested using this program, STEAMCYC, and some typical results are given. DOE

Progress is reported on the development of a new technique for measurement of trace levels of radioisotopes which is based on fluorescence detection of output from a mass spectrometer. Significant achievements include the observation of fluorescence and burst signals from Kr isotopes, including enriched samples of Kr-85 with a 4-collector system. An abundance sensitivity is demonstrated with Kr-83 and Kr-85. DOE

(DE95-006438; UCRL-JC-118859; CONF-941129-13) Avail: CASI HC A03/MF A01

Characteristic X rays have recently been explored as a method for the detection and identification of ions in accelerator mass spectrometry (AMS). After analysis in the AMS spectrometer, the ions stop in an appropriately chosen target and the induced X rays identify the ions by atomic number. For the application of AMS to higher mass isotopes, characteristic X rays allow significantly better discrimination of competing atomic isobars than is possible using energy loss detectors. Characteristic X rays also show promise as a convenient component in hybrid detection systems. Measurements of X ray yields are presented for Si, Fe, Ni, Se, Mo, and Pd ions of 0.5-2 MeV/AMU. The yields rise by more than a factor of 10 over this energy range, and approach 1 X-ray per incident ion at 2 MeV/AMU for the lighter ions. Preliminary work on the application of PXAMS to the detection of Se-79 is described. DOE

MODELING PRECIPITATION FROM CONCENTRATED SOLUTIONS WITH THE EQ3/6 CHEMICAL SPECIATION CODES
Lee F. Brown and Michael H. Ebinger 13 Jan. 1995 12 p Presented at the Waste Management '95 Conference, Tucson, AZ, 26 Feb. - 2 Mar. 1995
(Contract W-7405-eng-36)
(DE95-006264; LA-UR-95-201; CONF-950216-46) Avail: CASI HC A03/MF A01

One of the more important uncertainties of using chemical speciation codes to study dissolution and precipitation of compounds is the results of modeling which depends on the particular thermodynamic database being used. The authors goal is to investigate the effects of different thermodynamic databases on modeling precipitation from concentrated solutions. They used the EQ3/6 codes and the supplied databases to model precipitation in this paper. One aspect of this goal is to compare predictions of precipitation from ideal solutions to similar predictions from nonideal solutions. The largest thermodynamic databases available for use by EQ3/6 assume that solutions behave ideally. However, two databases exist that allow modeling nonideal solutions. The two databases are much less extensive than the ideal solution data, and they investigated the comparability of modeling ideal solutions and nonideal solutions. They defined four fundamental problems to test the EQ3/6 codes in concentrated solutions. Two problems precipitate Ca(OH)(sub 2) from solutions concentrated in Ca(++). One problem tests the precipitation of Ca(OH)(sub 2) from high ionic strength (high concentration) solutions that are low in the concentrations of precipitating species (Ca(++) in this case). The fourth problem evaporates the supernatant of the problem with low concentrations of precipitating species. The specific problems are discussed. DOE

NQR-NMR STUDIES OF HIGHER ALCOHOL SYNTHESIS Cu-Co CATALYSTS Quarterly Technical Progress Report, 15 Jun. 1994 - 15 Sep. 1994
U. A. Donatto, T. L. Hoard, and A. N. Murty 1995 10 p
(Contract DE-FG22-89PC-89761)
(DE95-007926; DOE/PC-89761/T10) Avail: CASI HC A02/MF A01

The selectivity and conversion efficiency of the catalyst are reported to be governed by inter-metallic ratios of the three elements. High yields of methanol in copper-rich field, hydrocarbons in cobalt-rich field and mixed alcohols in the intermediate range were observed. The basic mechanism, the extent and effect of inter-metallic interactions, or the role and function of chromium still remain unclear. To examine the correspondence between the catalytic and magnetic behavior of the catalyst, the author has investigated the Zero-field Nuclear Magnetic Resonance spectra and Hysteresis character of a series of Cu/Co/Cr trimetallics with Cu/Co ratio varying from 0.2 to 8.0. The magnetic moment of the catalyst system is very low for Cu/Co less than 1.5, dramatically increases when 1.5 less than Cu/Co less than 5.0 and drops for Cu/Co greater than 5.0. The NMR results indicate that chromium serves as a support and inhibits any strong intermetallic interaction between copper and cobalt. DOE

MATERIAL ANALYSIS USING COMBINED ELASTIC RECOIL DETECTION AND RUTHERFORD/ENHANCED RUTHERFORD BACKSCATTERING SPECTROMETRY
J. H. Burkhart (Idaho State Univ., Pocatello, ID.) and J. C. Barbour 1994 12 p Presented at the 13th International Conference on the Application of Accelerators in Research and Industry, Denton, TX, 7-10 Nov. 1994
(Contract DE-AC04-94AL-85000)
(DE95-005415; SAND-94-1885C; CONF-941129-12) Avail: CASI HC A03/MF A01

Three complimentary ion beam techniques will be combined in the analysis of oxide and nitride based materials, in particular BN/SiC and La(0.85)Sr(0.15)CoO(3). These materials can be synthesized over composition ranges which vary the physical and electrical properties, and therefore an accurate measure of the composition profiles is critical for controlling these properties. Elastic Recoil Detection (ERD) revealed the composition of light elements from H to O, and Rutherford Backscattering Spectrometry (RBS) gave the composition of heavier elements (e.g., Si, Sr, Co and La). Enhanced Rutherford Backscattering Spectrometry (FRBS) complimented these techniques by utilizing enhanced cross-sections, greater than Rutherford, to increase the signal-to-noise ratio for analysis of mid-range elements O, C, and N. ERD with 24 MeV Si ions gave profiles for H, B, and N in thin films, and 30 MeV Si was able to profile O in the top portion of heavier samples. Although 2.8 MeV He RBS worked well for heavier elements, ERBS utilized He ions at 3.5 MeV for N analysis and 8.7 MeV for O analysis, because at these energies the cross sections are 2 and 22 times Rutherford, respectively. Also, the depth of analysis was greater with ERBS because of the increased incident energy. DOE

NUMERICAL METHODS FOR DETERMINING INTERSTITIAL OXYGEN IN SILICON
J. O. Stevenson and J. W. Medernach Jan. 1995 39 p
(Contract DE-AC04-94AL-85000)
(DE95-007710; SAND-93-0349) Avail: CASI HC A03/MF A01

The interstitial oxygen (O(i)) concentration in Czochralski silicon and the subsequent SiO(x) precipitation are important parameters for integrated circuit fabrication. Uncontrolled SiO(x) precipitation during processing can create detrimental mechanical and electrical effects that contribute to poor performance. An inability to consistently and accurately measure the initial O(i) concentration in heavily doped silicon has led to contradictory results regarding the effects of dopant type and concentration on SiO(x) precipitation. The authors have developed a software package for reliably determining and comparing O(i) in heavily doped silicon. The SiFTIR(copyright) code implements three independent oxygen analysis methods in a single integrated package. Routine oxygen measurements are desirable over a wide range of silicon resistivities, but there has been confusion concerning which of the three numerical methods is most suitable for the low resistivity portion of the continuum. A major strength of the software is an ability to rapidly produce results for all three methods using only a single Fourier Transform Infrared Spectroscopy (FTIR) spectrum as input. This ability to perform three analyses on a single data set allows a detailed comparison of the three methods across the entire range of resistivities in question. Integrated circuit manufacturers could use the enabling technology provided by SiFTIR(copyright) to monitor O(i) content. Early detection of O(i) using this diagnostic could be beneficial in controlling SiO(x) precipitation during integrated circuit processing. DOE

A delaminated Fe2O3-pillared clay catalyst was prepared for the selective catalytic reduction (SCR) of NO by NH3 at above 300 C. The delaminated pillard clay was characterized by ICP-AES (Inductively Coupled Plasma-Atomic Emission Spectroscopy) chemical analysis, XRD (X ray diffraction) structure and line broadening analyses, micropore size probing, and Moessbauer analysis. These analyses showed that the catalyst contained fragmented Fe2O3- pillared clay forming (open 'house-of-cards' structure with dispersed Fe2O3 particles approximately 170 (angstrom) in size. The SCR activity of the delaminated pillard clay was higher than the commercial-type V2O5) + WO3/TiO2 catalyst, and also higher than the undelaminated pillard clay and supported Fe2O3 catalysts, under conditions with SO2. Infrared measurements of adsorbed NH3 showed strong Bronsted acidity which was caused possibly by interactions between Fe2O3 and clay. DOE

HIGH TEMPERATURE KINETIC STUDY OF THE REACTIONS H + O2 = OH + O AND O + H2 = OH + H IN H2/O2 SYSTEM BY SHOCK TUBE-LASER ABSORPTION SPECTROSCOPY Final Contractor Report
Si-Ok Ryu, Soon Muk Hwang, and Kenneth J. DeWitt Cleveland, OH NASA May 1995 123 p
(Grant NAG3-1307; RTOP 505-62-52)
(NASA-CR-195473; E-9670; NAS 1.26:195473) Avail: CASI HC A06/MF A02

The reactions: (1) H + O2 = OH + O; and (2) O + H2 = OH + H are the most important elementary reactions in gas phase combustion. They are the main chain-branching reaction in the oxidation of H2 and hydrocarbon fuels. In this study, rate coefficients of the reactions and have been measured over a wide range of composition, pressure, density and temperature behind the reflected shock waves. The experiments were performed using the shock tube - laser absorption spectroscopic technique to monitor OH radicals formed in the shock-heated H2/O2/Ar mixtures. The OH radicals were detected using the P(1)(5) line of (0,0) band of the A(exp 2) Sigma(+) from X(exp 2) Pi transition of OH at 310.023 nm (air). The data were analyzed with the aid of computer modeling. In the experiments great care was exercised to obtain high time resolution, linearity and signal-to-noise. The results are well represented by the Arrhenius expressions. The rate coefficient expression for reaction (1) obtained in this study is k(1) = (7.13 +/- 0.31) x 10(exp 13) exp(-6957+/- 30 K/T) cu cm/mol/s (1050 K less than or equal to T less than or equal to 2500 K) and a consensus expression for k(1) from a critical review of the most recent evaluations of k(1) (including our own) is k(1) = 7.82 x 10(exp 13) exp(-7105 K/T) cu cm/mol/s (960 K less than or equal to T less than or equal to 5300 K). The rate coefficient expression of k(2) is given by k(2) = (1.88 +/- 0.07) x 10(exp 14) exp(-6897 +/- 53 K/T) cu cm/mol/s (1424 K less than or equal to T less than or equal to 2427 K). For k(1), the temperature dependent A-factor and the correlation between the values of k(1) and the inverse reactant densities were not found. In the temperature range of this study, non-Arrhenius expression of k(2) which shows the upward curvature was not supported. Author

ABSORPTION OF SPARINGLY SOLUBLE GASES BY REACTIVE MEDIA IN SELF-AERATED GAS-LIQUID CONTACTORS: A SCALE-UP PROCEDURE
Yury Zundelevich Jan. 1995 18 p
(Contract W-7405-eng-48)
(DE95-006429; UCRL-ID-119563) Avail: CASI HC A03/MF A01

Absorption of sparingly soluble gases, such as NO or O2, is greatly enhanced if the latter react with the media. Among a dozen of reactive solvents for NO(x) abatement, aqueous acidic urea appears the most economically and environmentally attractive because urea is a cheap reagent and because products of reaction of urea with nitrous acid, formed in the liquid phase via absorption of NO and NO2, are carbon dioxide and nitrogen, which can be directly released into the atmosphere. That makes urea process unique among other wet scrubbing processes that routinely produce secondary waste. Its full potential has never been realized, perhaps due to the lack of an efficient gas-liquid contactor to overcome low solubility of NO in aqueous solutions. LLNL has recently designed and built a bench scale gas-liquid contactor for nitric acid regeneration with oxygen. The contactor proved very effective in overcoming the problem of low solubility of oxygen converting back to nitric acid approximately 99% of nitrous acid formed at the cathode (which would otherwise convert to NO(x). The bench scale contactor consists of a 12 inch diameter tank with self-inducting impeller/aerator of very high gas capacity. The aerator represents a 3.5 inch turbine mounted on a vertical shaft inside the draft tube equipped with a stator. During operation the lower half of the turbine induces liquid and the upper half induces gas from the draft tube. The new contactor offers two approaches to solving the NO(x) pollution problem. Where full recovery of nitric acid is desired, oxygen can be fed into the contactor to convert nitrous acid into nitric. This approach was demonstrated at LLNL. Alternately, in the proposed acidic urea process nitrous acid, as it forms from NO(x), would be converted to nitrogen, water and carbon dioxide. DOE

A COMPATIBILITY STUDY OF CONTAINMENT MATERIALS IN FEFO, BIS-(2-FLUORO-2,2-DINITROETHYL) FORMAL
T. J. Shepodd, S. H. Goods, W. E. Moddeman (Mason and Hanger-Silas Mason Co., Inc., Amarillo, TX.), and P. Foster (Mason and Hanger-Silas Mason Co., Inc., Amarillo, TX.) Feb. 1995 20 p
(Contract DE-AC04-94AL-85000)
(DE95-007548; SAND-94-8508) Avail: CASI HC A03/MF A01

We report on a program to evaluate the compatibility of energetic fluids with candidate containment materials. The energetic fluids are constituents of various extrudable explosives developed by Lawrence Livermore National Laboratory. These paste-like explosives consist of explosive particulates (HMX, TATB for example) suspended in mixtures of energetic liquids and are designed to remain extrudable over a wide temperature range for many years. It is important to preclude or minimize interactions between the constituents of the paste and the containment materials since such interactions could result in decreased reliability or failure of the containment vessel as well as intrinsic changes in the flow or explosive characteristics of the paste. In this report we focus on one specific paste formulation: RX-52-AE (Transferable Insensitive Explosive, TIE), composed principally of the solid explosive TATB and the energetic liquid, FEFO. Compatibility between a number of organic and metallic materials with neat FEFO has been evaluated. The 300 series stainless steels, Al 6061-T6, and Monel 400 showed evidence of surface attack (oxidation or pitting). Polished gold coupons became discolored and XPS analysis revealed the formation gold cyanide. Platinum, iridium, titanium, tantalum and Ta-10% W showed little evidence of reaction. Among the organic materials, the per-fluorinated materials showed only slight interaction with the FEFO while the polyethylene, polyester and Aclar(r) materials were attacked by the liquid. These interactions were manifested in changes in color, net weight gain and mechanical properties. The changes were exaggerated by higher temperatures. DOE

MAGNETIC AND STRUCTURAL PROPERTIES OF Fe/Pd MULTILAYERS STUDIED BY MAGNETIC X-RAY DICHROISM AND X-RAY ABSORPTION SPECTROSCOPY
S. M. Mini (Paris-Sud Univ., Orsay, France.), E. E. Fullerton, and C. H. Sowers Dec. 1994 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-31-109-eng-38)
(DE95-007095; ANL/MSD/CP-85324; CONF-941144-63) Avail: CASI HC A02/MF A01

The results of magnetic circular x-ray dichroism (MCXD) measurements and extended x-ray absorption fine structure measurements (EXAFS) of the Fe K-edges of textured Fe(110)/Pd(111) multilayers are reported. The EXAFS results indicate that the iron in the system goes from bcc to a more densely packed system as the thickness of the iron layer is decreased. The magnetic properties were measured by SQUID magnetometry from 5-350 K. For all the samples, the saturation magnetization was significantly enhanced over the bulk values indicating the interface Pd atoms are polarized by the Fe layer. The enhancement corresponds to a moment of approximately 2.5 mu(sub B) per interface Pd atom. DOE

THE SURFACE OF LIQUID He-4 AT NONZERO TEMPERATURES
K. A. Gernoth, J. W. Clark (Washington Univ., Saint Louis, MO.), and M. L. Ristig (Cologne Univ., Germany.) Jul. 1994 8 p
(DE95-607841; IC-94/160) Avail: CASI HC A02/MF A01 (US Sales Only)

We outline a general approach to microscopic evaluation of the properties of strongly interacting, spatially inhomogeneous Bose systems at finite temperature. A minimum principle for the Helmholtz free energy is used together with an appropriate trial density matrix to generalize the correlated variational wave function theory that has proven so successful in the treatment of the ground states and elementary excitations of quantum fluids at zero temperature. Euler-Lagrange equations are obtained that determine the optimal structure through the one-and two-body densities and the optimal density fluctuation operators and energies characterizing the elementary excitations. Some results of an application of this correlated density matrix theory to the He-4 liquid-vapor interface are presented, with particular focus on the characterization of resonant vapor modes. DOE

FTIR STUDIES OF CH3OH ON POROUS SILICON
John A. Glass, Jr., Edward A. Wovchko, and John T. Yates, Jr. Nov. 1994 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-1641)
(AD-A289038) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Fourier transform infrared spectroscopy (FTIR) was used to investigate the reaction of methanol with porous silicon and hydrogen passivated porous silicon. At 300 K methanol adsorbs onto hydrogen free porous silicon by cleavage of the O-H bond. Both of the resulting surface species, Si-H and Si-OCH3, were determined to be stable up to approx. 500 K. Above 500 K the Si-OCH3 moiety decomposes by breakage of the C-O and C-H bonds. The resulting carbon and oxygen were incorporated into the porous layer and additional Si-H surface species were detected. Further heating to 900 K removed the Si-H surface species. Adsorption of methanol onto hydrogen-passivated porous silicon did not occur until 600 K. At temperatures beyond 600 K, oxygen and carbon incorporation into the porous layer and Si-OCH3, Si-CH3, and Si-H surface species were seen. The previously unseen Si-CH3 surface species is believed to be stabilized by oxygen incorporation. DTIC

(Contract DE-FG02-86ER-13592)
(DE95-007071; DOE/ER-13592/9) Avail: CASI HC A01/MF A01

Efforts during the past year centered on expanding the understanding of the photocurrent transients produced by photoinduced dipoles in solution. In addition to exploring intramolecular charge transfer in a molecule which exhibits a giant dipole, the authors began an intensive look at intermolecular electron transfer between photoexcited electron donors and acceptors. The three projects which are farthest along are described in abstract form in the paragraphs which follow. The first makes use of the generous gift from Dr. Michael Wasielewski (Argonne National Laboratory) of a carefully constructed molecular triad which exemplifies artificial photosynthesis. Measurements reveal that the triad possesses a substantial ground state dipole moment as well as the long-lived charge separation which was expected for the excited state. The second and third abstracts describe the quantification of fractional charge transfer in excited state complexes (exciplexes). All exciplexes are not the same and the authors found that the fractional electron transfer increases with reaction exoergicity. The first and second abstracts describe work which is nearly ready to be submitted. The third outlines the mechanistically fascinating story of how one donor replaces another in an excited state complex. Their tentative conclusion is that the mechanism depends on reaction exoergicity. DOE

KINETICS AND DYNAMICS OF OXIDATION REACTIONS INVOLVING ADSORBED CO SPECIES ON BULK SUPPORTED Pt AND COPPER OXIDES Final Project Report, 1 Jan. 1991 - 31 Dec. 1993
Wm. C. Conner and M. Harold 1995 6 p
(Contract DE-FG02-87ER-13772)
(DE95-006420; DOE/ER-13772/T2) Avail: CASI HC A02/MF A01

This research was an integrated experimental and modeling study of oxidation reactions involving CO as a key player - be it a reactant, adsorbed intermediate, and/or partial oxidation product - in the catalytic sequence and chemistry. The reaction systems of interest in the project include CO, formaldehyde, and methanol oxidation by O2, and CO oxidation by NO, on both Pt and copper oxide catalysts. These reactions are of importance in automobile exhaust catalysis. There is a paucity of rate data in the literature for these important environmental control reactions. A complicating factor is the propensity of these reactions to exhibit complex steady state and dynamic behavior, including multiple rate controlling steps, steady state multiplicity, and oscillatory phenomena. Such phenomena are rooted in some of the central issues of catalysis, including edsorbate interactions, and catalyst structural instabilities, such as surface reconstruction and surface chemical changes by oxidation-reduction. The goal of this research is to better understand the catalytic chemistry and kinetics of oxidation reactions involving CO as an adsorbed intermediate. Successfully meeting this goal requires an integration of basic kinetic measurements, in situ catalyst surface monitoring, kinetic modeling, and nonlinear mathematical tools. While the kinetics experiments have standard microreactor design, the potential for multiple and periodic rate states demands detailed procedures to pinpoint the bifurcation (ignition, extinction, Hopf) points. Kinetic models are constructed from rational mechanistic sequences and sound surface chemistry. DOE

ELECTRICAL CONDUCTIVITY MEASUREMENTS OF AQUEOUS ELECTROLYTE SOLUTIONS AT HIGH TEMPERATURES AND HIGH PRESSURES

P. C. Ho and D. A. Palmer 1995 16 p Presented at the Conference on Properties of Water and Steam, Orlando, FL, 12 Sep. 1994
(Contract DE-AC05-84OR-21400)
(DE95-006748; CONF-9409219-5) Avail: CASI HC A03/MF A01

In aqueous solutions all electrolytes tend to associate at high temperatures (low dielectric constants). Ion association results in the formation of uncharged substrates, which are substantially more volatile than their precursor ions. Thus knowledge of the association constants is important in interpreting the thermodynamics of the partitioning of electrolytes to the vapor phase in a fully speciated approach. Electrical conductance measurements provide a unique window into ionic interactions of solutions at high temperatures and pressures. In this study, the electrical conductivities of dilute (less than 0.1 molal) aqueous solutions of NaCl (100-600 C to 300 MPa) and sodium and potassium hydroxides (0-600 and 100-600 C, respectively, and to 300 MPa) were measured. The results show that the extent of association of Na(+) and Cl(-) is similar to those for Na(+) and K(+) with OH(-) in solution from subcritical to supercritical conditions. DOE

AQUEOUS ELECTROLYTE MODELING IN ASPEN PLUS(TRADEMARK)

G. F. Bloomingburg, J. M. Simonson, R. C. Moore, R. E. Mesmer, and H. D. Cochran 1995 24 p Presented at the Conference on Properties of Water and Steam, Orlando, FL, 12 Sep. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007008; CONF-9409219-7) Avail: CASI HC A03/MF A01

The presence of electrolytes in aqueous solutions has long been recognized as contributing to significant departures from thermodynamic ideality. The presence of ions in process streams can greatly add to the difficulty of predicting process behavior. The difficulties are increased as temperatures and pressures within a process are elevated. Because many chemical companies now model their processes with chemical process simulators it is important that such codes be able to accurately model electrolyte behavior under a variety of conditions. Here the authors examine the electrolyte modeling capability of ASPEN PLUS(trademark), a widely used simulator. Specifically, efforts to model alkali metal halide and sulfate systems are presented. The authors show conditions for which the models within the code work adequately and how they might be improved for conditions where the simulator models fail. DOE

D/H AND O-18/O-16 PARTITIONING BETWEEN WATER LIQUID AND VAPOR IN THE SYSTEM H2O-Na-K-Mg-Ca-Cl-SO4 FROM 0 TO 350 C

J. Horita, D. J. Wesolowski, and D. R. Cole 1995 9 p Presented at the Conference on Properties of Water and Steam, Orlando, FL, 12 Sep. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007013; CONF-9409219-6) Avail: CASI HC A02/MF A01

Oxygen and hydrogen isotope partitioning between liquid water and water vapor has been precisely determined by means of direct mass-spectrometric measurements of isotopic abundances of the two phases from room temperature to 350 C. Measurable changes in the liquid-vapor partitioning were observed upon the addition of salts (NaCl, KCl, MgCl2, CaCl2, Na2SO4, and MgSO4) to the system. The results of isotope partitioning for the isotopic mixtures and the literature data of vapor pressure measurements of separate isotopic waters agree well for pure water, but show notable discrepancy for salt solutions. ANALYSIS OF THE DIMERIZED Sb/Si(001)-(2x1) SURFACE BY X-RAY STANDING WAVES

P. F. Lyman (Northwestern Univ., Evanston, IL.), Y. Qian, and M. J. Bedzyk (Northwestern Univ., Evanston, IL.) Dec. 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-31-109-eng-38)
(DE95-007097; ANL/MSD/CP-85241; CONF-941144-61) Avail: CASI HC A02/MF A01

X-ray standing wave measurements were undertaken to study the bonding position of Sb adatoms on the Sb-saturated Si(001)-(2 x 1) surface. Using the (004) and (022) Bragg reflections, the authors find that the Sb atoms form dimers, and that the center of the Sb ad-dimers lies 1.64 A above the bulk-like Si(004) surface atomic plane. These in-plane results are compared to two structural models consisting of dimers whose bonds are parallel to the surface plane and whose centers are either shifted or unshifted (parallel to the dimer bond direction) relative to the underlying substrate planes. The authors thus find two special cases consistent with these data: one with symmetric (unshifted) dimers having a dimer bond length of 2.81 A, and the other with midpoint-shifted dimers, having a bond length of 2.88 A and a lateral shift of 0.21 A. RESEARCH ON COMBUSTION PROCESSES RELEVANT TO BURNERS IN HVAC SYSTEMS Final Report, 1 Jul. 1991 - 31 Jul. 1994

S. R. Gollahalli Dec. 1994 200 p Sponsored by Gas Research Inst. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract GRI-5091-260-2178)
(PB95-179735; GRI-94/0420) Avail: CASI HC A09

An experimental investigation of the effects of using noncircular geometries for the fuel nozzles, primary-air venturi inlets, and burner exit ports in the inshot burners of residential natural gas heating systems is presented. These burners generally produce partially-premixed laminar flames. For global characterization, primary-air entrainment and exhaust emission indices of NO, NOx, and CO were measured. For detailed flame structure, radial profiles of temperature and major species concentration were recorded. Shadowgraphy was used for flow visualization. Most of the experiments were performed in lab-scale combustion chambers. Some verification tests were conducted in a full-scale furnace. The results show that, generally, primary-air premixing and secondary-air entrainment increase, and the NOx emission decreases for noncircular cross-sections. However, CO emission can increase in some of these cases. Deeper examination of the flow and chemistry coupling mediated by noncircular shapes is warranted before clear design paths of applying noncircular shapes are recommended. NTIS

VAPOR PRESSURES OF MIXTURES OF CFC-114 WITH THE POTENTIAL REPLACEMENT COOLANTS C4F(10) ANDc-C4F 8

L. D. Trowbridge and M. G. Otey (Paducah Gaseous Diffusion Plant, KY.) Sep. 1994 34 p Sponsored by United States Enrichment Corp.
(Contract DE-AC05-84OT-21400)
(DE95-003444; K/TCD-1118) Avail: CASI HC A03/MF A01

The U.S. Enrichment Corporation's production of isotopically enriched uranium depends solely on two plants which utilize the gaseous diffusion process. This process uses large quantities of CFC-114 as an evaporative coolant. CFC-114, however, will be phased out of production at the end of 1995 due to its potential to deplete stratospheric ozone. A search has been underway for substitutes for a number of years. The initial search (1988-89) for an ozone-friendly, commercially available, chemically compatible substitute yielded two candidates, FC-c318 (c-C4F8) and FC-3110 (C4F10). The intended mode of replacing coolant was to stage the new coolant into independent subsystems of the plants, so that some systems would continue to operate on CFC-114, and an increasing number would operate on the new coolant. During that changeover process, the possibility of coolant mixing arises in variety of scenarios. This work was intended to generate sufficient experimental information to be able to predict the vapor pressure of coolant mixtures over the range of operating conditions likely to be found in the diffusion plants. Specifically, vapor pressures were measured over the temperature range 322 to 355 K (120 F to 180 F) and over the full range of mole fractions for binary mixtures of CFC-114 with FC-3110, and of CFC-114 with FC-c318. DOE

BEYOND TRANSITION STATE THEORY: RIGOROUS QUANTUM APPROACHES FOR DETERMINING CHEMICAL REACTION RATES

W. H. Miller Jan. 1995 42 p
(Contract DE-AC03-76SF-00098)
(DE95-008483; LBL-36751) Avail: CASI HC A03/MF A01

Transition state theory (TST) has historically been the most important and widely used theoretical approach for describing the rates of chemical reactions, and for qualitative pictures and order-of-magnitude estimates one does not expect this situation to change. However a rigorous, quantitative treatment of chemical reaction rates must go beyond TST. A rigorous description, for example, must be based on a quantum mechanical description of the molecular system, but the fundamental assumption on which TST is based - namely that the molecular dynamics is 'direct,' i.e., that no trajectories recross a dividing surface which separates reactants and products (vide infra) - is couched inherently in the language of classical mechanics. There is no unambiguous way to quantize TST, for the various ways of trying to do so invariably require one to introduce additional assumptions about the reaction dynamics. As one tries to eliminate these 'additional assumptions' one is driven ultimately to an exact quantum treatment of the reaction dynamics which is then no longer a transition state theory (i.e., approximation) but simply an exact formulation. It is such exact approaches, those without inherent approximations, that are the subject of this chapter. DOE

BUBBLE CHAMBER SPECTROSCOPY FOR CHEMICAL ANALYSIS: A NEW CONCEPT
Jerry H. Atencio, Xin Luo, E. Iain McCreary, Andrew W. McCown, and Robert K. Sander 1995 8 p Presented at the SPIE 1995: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract W-7405-eng-36)
(DE95-006350; LA-UR-95-57; CONF-950226-19) Avail: CASI HC A02/MF A01

A new technique for the detection of trace concentrations of molecules in solution has been developed. This system utilizes the amplification characteristics of a bubble chamber in which energy deposition from laser absorption is monitored. In the experimental set-up, a trace quantity of solute is introduced into liquid propane that is contained in a small (10 ml) stainless steel cell at 120 psi. The propane is superheated by sudden reduction of the cell pressure. Before wall nucleated boiling occurs, target solute molecules are energized by a laser pulse. Absorption of pump laser energy results in the formation of nucleation centers which develop into bubbles and which in turn are detected by CCD camera. Preliminary experiments with crystal violet used as a test absorber have demonstrated detection sensitivity of 10 parts per trillion (ppt). DOE

TRANSPORT COEFFICIENTS FOR THE NASA LEWIS CHEMICAL EQUILIBRIUM PROGRAM
Roger A. Svehla Apr. 1995 29 p
(RTOP 505-62-52)
(NASA-TM-4647; E-9173; NAS 1.15:4647) Avail: CASI HC A03/MF A01

The new transport property data that will be used in the NASA Lewis Research Center's Chemical Equilibrium and Applications Program (CEA) is presented. It complements a previous publication that documented the thermodynamic and transport property data then in use. Sources of the data and a brief description of the method by which the data were obtained are given. Coefficients to calculate the viscosity, thermal conductivity, and binary interactions are given for either one, or usually, two temperature intervals, typically 300 to 1000 K and 1000 to 5000 K. The form of the transport equation is the same as used previously. The number of species was reduced from the previous database. Many species for which the data were estimated were eliminated from the database. Some ionneutral interactions were added. Author

VIBRATIONAL SPECTROSCOPY OF WATER INTERFACES Ph.D. Thesis
Q. Du Dec. 1994 133 p
(Contract DE-AC03-76SF-00098)
(DE95-006592; LBL-36546) Avail: CASI HC A07/MF A02

The second order nonlinear optical processes of second harmonic generation and sum frequency generation are powerful and versatile tools for studying all kinds of surfaces. They possess unusual surface sensitivity due to the symmetry properties of the second order nonlinear susceptibility. The technique of infrared-visible sum frequency generation (SFG) is particularly attractive because it offers a viable way to do vibrational spectroscopy on any surfaces accessible to light with submonolayer sensitivity. In this thesis, the author applies SFG to study a number of important water interfaces. At the air/water interface, hydrophobic solid/water and liquid/water interfaces, it was found that approximately 25% of surface water molecules have one of their hydrogen pointing away from the liquid water. The large number of unsatisfied hydrogen bonds contributes significantly to the large interfacial energy of the hydrophobic surfaces. At the hydrophilic fused quartz/water interface and a fatty acid monolayer covered water surface, the structure and orientation of surface water molecules are controlled by the hydrogen bonding of water molecules with the surface OH groups and the electrostatic interaction with the surface field from the ionization of surface groups. A change of pH value in the bulk water can significantly change the relative importance of the two interactions and cause a drastic change in orientation of the surface water molecules. SFG has also been applied to study the tribological response of some model lubricant films. Monolayers of Langmuir-Blodgett films were found to disorder orientationally under mildly high pressure and recover promptly upon removal of the applied pressure. DOE

HYDROGEN-ION TITRATIONS OF AMINO ACIDS AND PROTEINS IN SOLUTIONS CONTAINING CONCENTRATED ELECTROLYTE
F. Fergg, D. E. Kuehner, H. W. Blanch, and J. M. Prausnitz Dec. 1994 64 p
(Contract DE-AC03-76SF-00098)
(DE95-008356; LBL-36511) Avail: CASI HC A04/MF A01

This report describes a first attempt to quantify the net charge as a function of solution pH for lysozyme and (alpha)-chymotrypsin at 0.1 M, 1.0 M and 3.0 M ionic strength, (IS). The calculations are based on the residue (titratable group) pK(sub a)'s in the amino-acid sequence of the protein. To determine these pK(sub a)'s, a simple theory was used which assumes that the pK(sub a)'s are independent from each other in the protein and are equal to their pK(sub a) values in free amino-acid solution (Independent-Site Theory, IST). Residue pK(sub a)'s were obtained from amino-acid hydrogen-ion titrations at three different KCl concentrations corresponding to 0.1M, 1.0M and 3.0M ionic strength. After construction of a suitable apparatus, the experimental procedure and data reduction were computerized to perform a large number of titrations. Most measured pK(sub a)'s showed high reproducibility (the difference of pK(sub a) values observed between two experiments was less than 0.05). For IS = 0.1M, observed pK(sub a)'s agreed with literature values to within a few hundredths of a pH unit. Furthermore, the ionic-strength dependence of the pK(sub a)'s followed the trends reported in the literature, viz. pK(sub a) values decrease with increasing ionic strength until they reach a minimum at about IS = 0.5M. At still higher IS, pK(sub a)'s increase as the ionic strength rises to 3M. The known pK(sub a)'s of all titratable groups in a protein were used with the IST to give a first approximation of how the protein net charge varies with pH at high ionic strength. A comparison of the titration curves based on the IST with experimental lysozyme and (alpha)-chymotrypsin titration data indicates acceptable agreement at IS = 0.1M. However, comparison of measured and calculated titration curves at IS = 1M and IS = 3M indicates only quantitative agreement. DOE

MECHANISM OF DEPOSIT FORMATION ON FUEL-WETTED HOT METAL SURFACES Interim Report, May 1989 - Dec. 1992
Leo L. Stavinoha, Steven R. Westbrook, and Lona A. McInnis Jan. 1995 91 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts DAAK70-87-C-0043; DAAK70-92-C-0059)
(AD-A289847; BFLRF-290) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Experiments were performed in a Single-Tube Heat Exchanger (STHE) apparatus and a Hot Liquid process meet Jet Fuel Thermal Oxidation Tester (JFTOT) ASTM D 3241 requirements. The HLPS-JFTOT heater tubes used were 1018 mild steel, 316 stainless steel (SS) 304 SS, and 304 SS tubes coated with aluminum, magnesium, gold, and copper. A low-sulfur was used to create deposits on the heater tubes at temperatures of 300 C, 340 C, and 380 C. Deposit thickness was measured by dielectric breakdown voltage and Auger ion milling. Pronounced differences between the deposit thickness measuring techniques suggested that both Auger milling rate and the dielectric strength of the deposit may be affected by deposit morphology/composition (such as metal ions that have become included in the bulk of the deposit). Carbon burnoff data were obtained as a means of judging the validity of DMD-derive deposit evaluations. ESCA data suggest that the thinnest deposit was the magnesium-coated test tube. The scanning Electron Microscope (SEM) photographs showed marked variations in the deposit morphology and the results suggested composition has a significant effect on the mechanism of deposition. PHOTOEMISSION STUDY OF SOLID STATE REACTION AND INITIAL OXIDATION OF THE Ce/Al(100) SYSTEM Journal Article
C. Berg, S. Raaen, and A. Borg 19 May 1994 11 p Prepared in cooperation with Trondheim Univ.
(PB95-195368; STF19-S94003) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

High resolution photoemission spectroscopy has been used to study interface formation and initial oxidation of the Ce/Al(111) system at room temperature and at approximately 100 K. Both the evolution of the interface layer and the initial oxide growth have been investigated in detail. Evaporated Ce overlayers in the range 1-8 Angstroms were found to interdiffuse with Al(111) to form a mixed interface with at least three different Ce-Al coordinations. At room temperature, one of the Ce-Al coordinations predominates as the mixed layer grows. At 100 K a wide variation of Ce-Al coordination is observed, but none of these is preferred during growth. (IFTR-32/1994) Avail: Issuing Activity (Polish Academy of Sciences, Warsaw, Poland)

The purpose of this study was to evaluate the properties of the low-alloy structural steel known as 18G2A steel after a program of cyclical loading on the basis of skeleton curves. Tests were conducted using thin-walled tubular specimens in a planar stress state produced by different combinations of axial force and torque. The properties of the material as supplied were estimated on the basis of plasticity surface determined by testing a large number of samples and served as a reference point for comparing the changes in the properties of the material caused by intentional cyclical deformation. The authors propose a new concept for evaluating the properties of a material subjected to cyclical deformation based on the determination of the so-called cyclical plasticity surface. The cycling loading program used by the authors, which included constant loads and loads of diminishing amplitude, caused the steel to weaken in the range of plastic deformations studied, with the most weakening occurring in the directions in which the cyclical loading was applied. The authors' tests revealed that the material in question, which as supplied had anisotropic plastic properties, exhibited the same degree of weakening for each direction analyzed under the impact of the cyclical loading program.

CHARACTERIZATION OF ULTRA-LOW CARBON BAINTIC STEELS FOR USE AS WELD WIRE CONSUMABLES M.S. Thesis

Michael L. Beno Sep. 1994 97 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00167-94-WR-40321; N00014-94-WX-35069)
(AD-A288292) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The use of Ultra-Low Carbon Bainitic (ULCB) steels for weld wire applications is an area of current interest to the U. S. Navy and is being jointly studied by the Naval Postgraduate School and the Naval Surface Warfare Center, Annapolis, MD. The focus of the present work is to determine the effect of macrostructure, microstructure, and the size, distribution and chemical composition of the non-metallic inclusions on the strength and impact toughness of multipass Gas Metal Arc (GMA) and Gas Tungsten Arc (GTA) welds. Eight sample multipass GMA and GTA weldments using ULCB weld wire were studied by optical, scanning electron and transmission electron microscopy (SEM and TEM). The microstructures of the weld metals were dominantly bainitic except for the recrystallized regions of the GTA welds which had become ferritic. The macrostructure of the GMA weldments was dominated by columnar grains. SEM and optical fractography suggested that this macrostructure is responsible for the corresponding poor toughness in these weldments. In all weldments the non-metallic inclusions were found to be very small (on average % 0.5 microns) with a somewhat higher volume fraction in the GMA vice GTA weldments. Based on previous work, the small average size of these inclusions are surmised to have had very little effect on toughness. DTIC

ELASTIC PROPERTIES OF METALLIC SUPERLATTICES Final Report

Charles M. Falco and George I. Stegeman 30 Nov. 1994 8 p Revised Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-88-K-0298; N00014-91-J-1104)
(AD-A288699) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This Final Report describes some of the significant results from our research program on the elastic properties of metallic multilayers and superlattices. The elastic properties of composition-modulated metallic superlattice films have received considerable attention over the past fifteen years following the initial reports of anomalous enhancements of some elastic moduli as measured by the bulge tester method. For example, it was reported that the Ag/Pd system exhibited an increase of the biaxial modulus of up to 500%. However, more recent measurements failed to reproduce such large enhancements of elastic moduli in the systems for which the elastic anomaly was originally measured. The elastic anomalies observed in subsequent experiments were considerably smaller, although they showed a functional dependence on lambda with either stiffening or softening taking place in different material systems for lambda in the range of approximately 25-40 A. In apparent contrast, some Brillouin light scattering (BLS) measurements have shown a softening of the shear elastic constant C(sub 44) in some bcc/fcc systems, although a stiffening was found in Au/Cr. Because of these apparent contradictions, coupled with the importance of this problem, we initiated a program with ONR funding to investigate these effects. In this report, we review some of our significant results obtained with ONR funding, on the structural and elastic properties observed metallic superlattice films. DTIC

IDENTIFICATION OF THE PLASTIC ANISOTROPY OF AN ALUMINUM ALLOY [IDENTYFIKACJA PLASTYCZNEJ ANIZOTROPII STOPU ALUMINIUM]

Lech Dietrich, Romuald Kiryk, Grzegorz Socha, and Marek Sliwowski 1994 50 p In POLISH
(ISSN 0208-5658)
(IFTR-26/1994) Avail: Issuing Activity (Polish Academy of Sciences, Warsaw, Poland)

This article contains the results of experimental studies in complex stress states produced on thin-walled tubular specimens subjected to different combinations of simultaneously operating axial force (tensile or compressive) and bi-directional torque. The specimens were prepared from complete extruded rods of PA6 aluminum alloy. The basic purpose of this study was to identify the type of plastic anisotropy and calculate its coefficients on the basis of tests in complex stress states using a large number of specimens, each of which was subjected to loading along different proportional paths in the stress pace under consideration. The author used Mises' (1928) anisotropic condition of plasticity in an updated version which accounts for the Bauschinger effect to approximate the experimental points which describe the shape and location of the materials' plasticity surface. The authors also compared the plasticity surface determined in this way with surfaces obtained in the basis of a frequently used streamlined test procedure in which only a single specimen is successively subjected to different stress states.

An experimental analysis of the plastic properties of electrolytic copper in its original condition and subjected to different types of initial deformation is presented. The analysis was based on the location and dimensions of plasticity surfaces determined. In the first phase of the study, the authors determined the original surface by a method involving alternating and identical holes in the same specimen, which served as a starting point for comparisons of plastic surfaces determined for the same material after intentional deformation. In subsequent phases of the study, the authors applied the same initial deformations under creep at a constant elevated temperature and a constant stress level and under monotonic loading at room temperature. After the specimens were deformed to the extent specified in advance, the authors determined their plasticity surfaces using the same method of alternating holes as they did in determining the original surface. The experimental results were then approximated under the assumption of an anisotropic plasticity condition. Transl. by Schreiber Translations Inc.

(IFTR-27/1994) Avail: Issuing Activity (Polish Academy of Sciences, Warsaw, Poland)

This article contains the results of experiments concerning the effect of multi-axial cyclical plastic deformation on the changes in the anisotropy constants of PA6 aluminum alloy in a planar stress state. The experiments were performed on thin-walled tubular specimens subjected to simultaneous loading with a combination of axial force and reversible torque. The specimens were prepared from rods as supplied by the mill and studies of their original plasticity surface confirmed the high anisotropy of the alloy, which it had acquired in the manufacturing process. The primary purpose of this study was to determine the vulnerability of the material with its original texture to multi-directional cyclical plastic deformation in plastic working. The authors' tests revealed that the plastic behavior of the alloy is highly dependent on the direction of the initial cyclical loading relative to the axis of anisotropy associated with the axis of the rod. The authors found that complex multi-directional cyclical loading does not cause any change in the main axis of anisotropy associated with the axis of the specimen. The authors also discovered that there was no rotation of the plasticity surfaces corresponding to all the directions of initial deformation. The only effect that the direction of initial cyclical loading had was on the size of the axis of the plasticity surface aligned with the axis of the rod, while the changes in the axis of the plasticity surface perpendicular to the main axis of anisotropy were negligible. For purposes of comparison, the authors indicate that cyclical plastic deformation results in greater changes in the dimensions of the plasticity surface than the equivalent monotonic plastic deformation. FATIGUE FRACTURE ANALYSIS IN MEDIUM CARBON STRUCTURAL STEEL AND AUSTENITIC STAINLESS STEEL BY X-RAY FRACTOGRAPHY

N. N. Rao and Azmi binRahmat 1994 26 p Presented at the National Seminar on the Assessment of IRPA Research Achievement in 5th Malaysian Plan, Kedah, Malaysia, 20-24 Dec. 1991

(DE95-601504; INIS-MF-13965; CONF-9112185) Avail: CASI HC A03/MF A01 (US Sales Only)

Apart from the residual stresses present in the bulk material, a growing fatigue crack may develop its own stress field ahead of the crack tip which in turn could influence the crack propagation behaviour. A fracture surface analysis through measurement of the residual stress of a failed component may provide some additional useful information to that obtained through conventional metallurgical and fracture mechanics investigations. This method of fracture surface analysis using x-ray diffraction technique is known as 'X-ray Fractography'. Residual stress ((rho) sub (gamma)) and the full width at half maximum (FWHM) of the x-ray diffraction profile of any reflection are determined at different crack lengths on the fracture surface. These are then correlated to the fracture toughness parameters such as fracture toughness K(sub IC), the maximum stress intensity factor K(sub max) and the stress intensity factor range (delta)K. The present investigation aims at detailed x-ray analysis of the fatigue fractured surfaces of the compact tension specimens prepared from ferritic and austenitic stainless steels. The ferritic steel has been subjected to various heat treatments to obtain different microstructures and mechanical properties. The overall observations are analyzed through fatigue (cumulative) damage and material science concepts. DOE

LATTICE PARAMETERS AND DEBYE-WALLER FACTORS OF GAMMA-TIAI ALLOYS

Sarath K. Menon and Alan G. Fox Dec. 1994 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract FY1457-94-N5026)

(AD-A288843; NPS-ME-94-009) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Accurate lattice parameters of the tetragonal gamma-TiAl phase with the L1(0) structure have been determined by X-ray diffraction. The results showed that in binary alloys, the A parameter decreases while the C parameter increases with increasing Al content. Integrated X-ray intensities were determined from annealed powder samples with powder size less than 5 microns in order to estimate the temperature factors. Difficulties associated with such evaluations due to the effects of extinction are also discussed. In addition, the 110, 111, and 200 structure factor amplitudes of gamma-phase Ti-56 at.% Al alloy were accurately determined from critical-voltage electron diffraction measurements. The Debye-Waller factors determined from X-ray experiments and the critical voltage experiments are compared and the results discussed. DTIC

ANNEALING-INDUCED CHANGES IN THE ANISOTROPY OF AN ALUMINUM ALLOY [ZMIANY ANIZOTROPII STOPU ALUMINIUM POD WPLYWEM WYZARZANIA]

Lech Dietrich, Romuald Kiryk, and Karol Turski 1994 41 p In POLISH (ISSN 0208-5658)

(IFTR-24/1994) Avail: Issuing Activity (Polish Academy of Sciences, Warsaw, Poland)

Tubular specimens of PA6 alloy annealed at two different temperatures were tested under loading consisting of axial force and torque. The authors observed uneven changes in plastic anisotropy after annealing at different temperatures. The authors plotted the plasticity surfaces and ranges of variation of their parameters as functions of the annealing temperature. Plasticity surfaces may be described as an ellipse with an axis ratio which changes between 2 to 1.95 with an increase in annealing temperature.

An INVAR 36 material having long-term dimensional stability is produced by sintering a blend of powders of nickel and iron under pressure in an inert atmosphere to form an alloy containing less than 0.01 parts of carbon and less than 0.1 part aggregate and preferably 0.01 part individually of Mn, Si, P, S and Al impurities. The sintered alloy is heat treated and slowly and uniformly cooled to form a material having a coefficient of thermal expansion of less than 1 ppm/C and a temporal stability of less than 1 ppm/year. The objective of this integrated research program is to define the conditions under which high strength Beta-titanium alloys resist environmentally assisted cracking (EAC) in marine environments. Specific goals are to: (1) characterize EAC for metallurgical, chemical, and mechanical conditions that could destabilize crack tip passive films to promote local dissolution and hydrogen uptake, (2) test the hydrogen embrittlement mechanism for EAC, and (3) develop a mechanism-based model of EAC by integrating crack chemistry, surface dissolution and repassivation kinetics, hydrogen uptake to trap sites, and crack tip process zone micromechanics and damage. This final report presents a summary of the results and includes papers published during the period of this grant from Sep. 1991 to Sep. 1994. DTIC

FIRST-PRINCIPLES STUDY OF INTERMETALLIC PHASE STABILITY IN THE TERNARY Ti-Al-Nb ALLOY SYSTEM

M. Asta, A. Ormeci, J. M. Wills, and R. C. Albers 1995 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994

(Contract W-7405-eng-36)

(DE95-005259; LA-UR-94-4079; CONF-941144-46) Avail: CASI HC A02/MF A01

The stability of bcc-based phases in the Ti-Al-Nb alloy system has been studied from first-principles using a combination of ab-initio total energy and cluster variation method (CVM) calculations. Total energies have been computed for 18 binary and ternary bcc superstructures in order to determine low temperature ordering tendencies. From the results of these calculations a set of effective cluster interaction parameters have been derived. These interaction parameters are required input for CVM computations of alloy thermodynamic properties. The CVM has been used to study the effect of composition on finite-temperature ordering tendencies and site preferences for bcc-based phases. Strong ordering tendencies are observed for binary Nb-Al and Ti-Al bcc phases as well as for ternary alloys with compositions near Ti2AlNb. For selected superstructures we have also analyzed structural stabilities with respect to tetragonal distortions which transform the bcc into an fcc lattice. Instabilities with respect to such distortions are found to exist for binary but not ternary bcc compounds. DOE

EFFECTS OF HELIUM PRE-IMPLANTATION ON THE MICROSTRUCTURE AND MECHANICAL PROPERTIES OF IRRADIATED 316 STAINLESS STEEL
M. B. Toloczko, G. R. Tedeski, G. E. Lucas, G. R. Odette, R. E. Stoller, and M. L. Hamilton Nov. 1994 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-AC06-76RL-01830; DE-FG03-87ER-52143; DE-AC05-84OR-21400)
(DE95-007162; PNL-SA-25670; CONF-941144-60) Avail: CASI HC A02/MF A01

Transmission electron microscopy (TEM) specimens of a First Core heat of 316 stainless steel, in both the solution annealed and 20% cold worked condition, were irradiated to 46 dpa at 420 C, to 49 dpa at 520 C, and to 34 dpa at 600 C in FFTF/MOTA. Prior to irradiation, about half of the specimens were pre-implanted with approximately 100 appm of helium, and of these, several of the solution annealed and pre-implanted specimens were aged at 800 C for 2 hr. Post-irradiation density measurements showed little difference in density between the unimplanted alloys and their helium implanted counterparts. Microstructural observations on specimens irradiated at 420 C and 520 C showed relatively minor differences in defect distributions between the unimplanted and the helium implanted materials; in all cases the defect sizes and number densities were consistent with data in the literature. Where possible, irradiation hardening of the alloys was experimentally evaluated by microhardness and shear punch; experimentally obtained values were compared to values calculated using a computer model based on barrier hardening and the microstructural data. All methods indicated relatively small effects of helium implantation, and both measured and calculated values were in agreement with the range of values reported in the literature. DOE

SIMULATING THE PRODUCTION OF FREE DEFECTS IN IRRADIATED METALS
H. L. Heinisch Jul. 1994 14 p Presented at the 2nd International Conference on Computer Simulation of Radiation Effects, Santa Barbara, CA, 24-29 Jul. 1994
(Contract DE-AC06-76RL-01830)
(DE95-007165; PNL-SA-24441; CONF-940731-4) Avail: CASI HC A03/MF A01

Under cascade-producing irradiation by high energy neutrons or charged particles, only a small fraction of the initially displaced atoms contribute to the population of free defects, i.e. those that are available to migrate throughout the metal and cause microstructural changes. Although, in principle, computer simulations of free defect production could best be done using molecular dynamics, in practice, the wide ranges of time and distance scales involved can be done only by a combination of atomistic models that employ various levels of approximation. An atomic-scale, multimodel approach has been developed that combines molecular dynamics, binary collision models and stochastic annealing simulation. The annealing simulation is utilized in calibrating binary collision simulations to the results of molecular dynamics calculations, as well as to model the subsequent migration of the defects on more macroscopic time and size scales. The annealing simulation and the method of calibrating the multimodel approach are discussed, and the results of simulations of cascades in copper are presented. The temperature dependence of free defect production following simulated annealing of isolated cascades in copper shows a differential in the fractions of free vacancies and interstitial defects escaping from the cascade above Stage V. This differential, a consequence of the direct formation of interstitial clusters in cascades and the relative thermal stability of vacancy and interstitial clusters du ring subsequent annealing, is the basis for the production bias mechanism of void swelling. PROBABILISTIC MATERIAL STRENGTH DEGRADATION MODEL FOR INCONEL 718 COMPONENTS SUBJECTED TO HIGH TEMPERATURE, HIGH-CYCLE AND LOW-CYCLE MECHANICAL FATIGUE, CREEP AND THERMAL FATIGUE EFFECTS Final Technical Report, Jun. 1992 - Jan. 1995
Callie C. Bast and Lola Boyce Jan. 1995 86 p
(Grant NAG3-867)
(NASA-CR-197832; NAS 1.26:197832) Avail: CASI HC A05/MF A01

This report presents the results of both the fifth and sixth year effort of a research program conducted for NASA-LeRC by The University of Texas at San Antonio (UTSA). The research included on-going development of methodology for a probabilistic material strength degradation model. The probabilistic model, in the form of a postulated randomized multifactor equation, provides for quantification of uncertainty in the lifetime material strength of aerospace propulsion system components subjected to a number of diverse random effects. This model is embodied in the computer program entitled PROMISS, which can include up to eighteen different effects. Presently, the model includes five effects that typically reduce lifetime strength: high temperature, high-cycle mechanical fatigue, low-cycle mechanical fatigue, creep and thermal fatigue. Statistical analysis was conducted on experimental Inconel 718 data obtained from the open literature. This analysis provided regression parameters for use as the model's empirical material constants, thus calibrating the model specifically for Inconel 718. Model calibration was carried out for five variables, namely, high temperature, high-cycle and low-cycle mechanical fatigue, creep and thermal fatigue. Methodology to estimate standard deviations of these material constants for input into the probabilistic material strength model was developed. Using an updated version of PROMISS, entitled PROMISS93, a sensitivity study for the combined effects of high-cycle mechanical fatigue, creep and thermal fatigue was performed. Then using the current version of PROMISS, entitled PROMISS94, a second sensitivity study including the effect of low-cycle mechanical fatigue, as well as, the three previous effects was performed. Results, in the form of cumulative distribution functions, illustrated the sensitivity of lifetime strength to any current value of an effect. In addition, verification studies comparing a combination of high-cycle mechanical fatigue and high temperature effects by model to the combination by experiment were conducted. Thus, for Inconel 718, the basic model assumption of independence between effects was evaluated. Results from this limited verification study strongly supported this assumption. Author

STRESS CORROSION CRACKING SUSCEPTIBILITY OF THE EARTHQUAKE RESISTANT NOM B457 MEXICAN STEEL Ph.D. Thesis
Carlos Rosendo ArganisJuarez 1994 215 p
(DE95-607956; INIS-mf-14408) Avail: CASI HC A10/MF A03 (US Sales Only)

The Mexican construction code was modified after the Mexico city 1985 earthquake, substituted the medium carbon reinforced steel NOM B6 by the new micro alloyed steel NOM B457 in 42 Kg/sq mm grade. The present study reports the evaluation of the NOM B457 steel behavior in mortar with and without 2% wt. in chlorides and in Ca(OH)2 saturated solutions. The results are compared with the NOM B6 steel behavior in the same conditions. The Stress Corrosion Cracking (SCC) is not present in all the conditions used in this study and there are not susceptibility potential range to SCC when the material is evaluated by electrochemical Tests, Constant Extension Rate Tests (CERT) and Constant Load Test at

80% of yield stress. A susceptibility potential range to Hydrogen Induced Cracking (HIC) is detected, below -900 mV. vs Standard Calomel Electrode (SCE) by CERT at constant potential. DOE

NON-METALLIC OXIDE INCLUSION FORMATION IN C-MnLOW ALLOY STEEL WELDS
S. S. Babu (Pennsylvania State Univ., University Park, PA.), K. Mundra (Pennsylvania State Univ., University Park, PA.), T. DebRoy (Pennsylvania State Univ., University Park, PA.), S. A. David, and J. M. Vitek 1995 3 p Presented at the 76th American Welding Society Convention, Cleveland, OH, 2-7 Apr. 1995
(Contract DE-AC05-84OR-21400)
(DE94-019160; CONF-950443-1) Avail: CASI HC A01/MF A01

Inclusion characteristics influence weld metal microstructure development, especially the formation of high toughness acicular ferrite phase. Important inclusion characteristics are: size distribution, number density, volume fraction, and composition. Previous work considered a sequential formation of various oxides and compounds to estimate the inclusion characteristics; however, effects of weld metal composition, nucleation, and growth conditions on inclusion formation were ignored. In this work, the principles of ladle deoxidization and transformation kinetics involving nucleation and growth are used to estimate the inclusion characteristics as a function of weld metal composition and cooling conditions. (Contract DE-AC09-89SR-18035)
(DE95-006464; WSRC-MS-94-0612) Avail: CASI HC A03/MF A01

The United States Department of Energy owns large quantities of radiologically contaminated austenitic stainless steel which could by recycled for reuse if appropriate release standards were in place. Unfortunately, current policy places the formulation of a release standard for USA industry years, if not decades, away. The Westinghouse Savannah River Company, Idaho National Engineering Laboratory and various university and industrial partners are participating in initiative to recycle previously contaminated austenitic stainless steels into containers for the storage and disposal of radioactive wastes. This paper describes laboratory scale experiments which demonstrated the decontamination and remelt of stainless steel which had been contaminated with radionuclides. DOE

ATOMISTIC STUDY OF ENERGY AND STRUCTURE OF SURFACES IN NIO
M. Yan, S. P. Chen, A. F. Voter, and T. E. Mitchell 1994 8 p
Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-7405-eng-36)
(DE95-005207; LA-UR-94-4219; CONF-941144-41) Avail: CASI HC A02/MF A01

The structure and energy of surfaces in NiO have been studied by atomistic calculations employing short range Buckingham potentials fitted to properties of NiO. The polarizability of lattice anions is included by using the shell model. The results show that the surface energy depends strongly on surface orientation, and the 100 surface has the lowest energy. Surfaces with higher energy prefer to reconstruct into 100 facets to lower their energy and to stabilize their structure. DOE

TENSILE PROPERTIES OF Fe-16 AT. % Al ALLOYS
V. K. Sikka 1995 19 p Presented at the 8th Annual Conference on Fossil Energy Materials, Oak Ridge, TN, 10-12 May 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC05-84OR-21400)
(DE95-007102; CONF-9405143-9) Avail: CASI HC A03

A newly developed melting method for Fe-16 at. % Al alloy (FAPY) is described. Tensile data on the air-induction-melted (AIM) and vacuum-induction-melted (VIM) heats of FAPY after identical processing are presented. Optical, scanning electron micrographs (SEM), and microprobe analysis were carried out to explain the lower room-temperature ductility and more scatter in the data for the AIM material as opposed to the VIM material. Elastic neutron-scattering measurements on two samples of Cu alloyed with 1.3% Mn and 0.55% Mn show that the spin-density-wave (SDW) features found in more concentrated alloys persist in the limit of very dilute alloys. These features consist of temperature-dependent incommensurate peaks in magnetic neutron scattering, with positions and strengths which are fully consistent with those in the concentrated alloys. The implications of these measurements are twofold. First, it is clear from this data that SDW magnetic ordering occurs across the entire range of CuMn alloys which have typically been interpreted as spin glasses. Second, the more fundamental significance of this work is the suggestion via extrapolation that a peak in the magnetic susceptibility x(q) occurs in pure copper, at a value of q given by the Fermi-surface diameter 2k(sub F). C15 INTERMETALLIC COMPOUNDS HfV2+Nb
F. Chu, S. P. Chen, T. E. Mitchell, D. P. Pope (Pennsylvania Univ., Philadelphia, PA.), and C. T. Liu (Oak Ridge National Lab., TN.) 1994 7 p Presented at the IUMRS International Conference in Asia, Hsinchu, HI, 14-18 Dec. 1994
(Contract W-7405-eng-36)
(DE95-005264; LA-UR-94-4288; CONF-941252-1) Avail: CASI HC A02/MF A01

Phase fields and equilibria in the Hf-V-Nb system were determined using a combination-of SEM, EDS and x ray diffraction. The structural stability of the C15 HfV2(+)Nb was studied by x ray diffraction and specific heat measurements. The elastic constants of C15 HfV2(+)Nb were measured by the resonant ultrasound spectroscopy technique. First-principle quantum mechanical calculations based on the local-density-functional theory have been employed to study the total energy and electronic structure of C15 HfV2, which can be used to understand the physical and metallurgical properties of the C15 intermetallics HfV2(+)Nb. ADVANCED NEUTRON SOURCE MATERIALS SURVEILLANCE PROGRAM
S. M. Heavilin (Purdue Univ., West Lafayette, IN.) Jan. 1995 37 p
(Contract DE-AC05-84OR-21400)
(DE95-005700; ORNL/M-3733) Avail: CASI HC A03/MF A01

The Advanced Neutron Source (ANS) will be composed of several different materials, one of which is 6061-T6 aluminum. Among other components, the reflector vessel and the core pressure boundary tube (CPBT), are to be made of 6061-T6 aluminum. These components will be subjected to high thermal neutron fluences and will require a surveillance program to monitor the strength and fracture toughness of the 6061-T6 aluminum over their lifetimes. The purpose of this paper is to explain the steps that were taken in the summer of 1994 toward developing the surveillance program. The first goal was to decide upon standard specimens to use in the fracture toughness and tensile testing. Second, facilities had to be chosen for specimens representing the CPBT and the reflector vessel base, weld, and heat-affected-zone (HAZ) metals. Third, a timetable had to be defined to determine when to remove the specimens for testing. DOE

AEM INVESTIGATION OF TETRAHEDRALLY COORDINATED Ti(4+) IN NICKEL-TITANATE SPINEL

I. M. Anderson, J. Bentley, and C. B. Carter (Minnesota Univ., Minneapolis, MN.) 1994 7 p Presented at the Fall Meeting of the Materials Research Society (MRS), Boston, MA, 29 Nov. - 3 Dec. 1993
(Contract DE-AC05-84OR-21400)
(DE95-006624; CONF-931108-113) Avail: CASI HC A02/MF A01

Stoichiometry and site distribution of metastable nickel-titanate spinel was studied with AEM. Results of EDXS and EELS agree that the metastable spinel is nonstoichiometric and titanium-deficient relative to its hypothetical endmember composition, 'Ni2TiO4'. The titanium deficiency ha s been determined by EELS to be (Delta) = 0.025 +/- 0.005. Channeling-enhanced microanalysis and ELNES studies indicate that the Ti(4+) and Ni(2+) cations are in tetrahedral and octahedral coordination, respectively, so that the metastable spinel has the normal cat on distribution: Ti(sub I-(Delta))(Ni2(1+(Delta))) O(sub 4). This is consistent with neutron powder-diffraction studies and SiO2-solubility measurements of similar equilibrated and quenched spinel-containing specimens. Metastable nickel-titanate spinel therefore contrasts with stable stoichiometric spinels which tend to the inverse cation distribution, Me(MeTi)O4). DOE

LASER ULTRASONIC GENERATION AT THE SURFACE OF A LIQUID METAL

J. B. Walter, K. L. Telschow, and R. J. Conant (Montana State Univ., Bozeman, MT.) 1995 6 p Presented at the Review of Progress in Quantitative Nondestructive Examination, Snowmass, CO, 1-5 Aug. 1994
(Contract DE-AC07-76ID-01570)
(DE95-004999; EGG-M-94170; CONF-9408208-1) Avail: CASI HC A02/MF A01

The noncontacting nature of laser-based ultrasonic measurement has made it attractive in many applications. While most applications thus far involve solid samples, molten metals encountered in some stages of metal processing appear well suited to this technique. Possible applications for liquid metals include locating and characterizing the liquid/solid interface; characterizing a surface layer, contaminant, or alloying constituent; and measuring the temperature of the sample surface or bulk. This work aimed to characterize laser generation of ultrasound in liquid metals to facilitate the development of techniques for these applications. This paper describes measurements of the angular distribution and energy dependence of laser-generated ultrasound in mercury at ambient temperature. Mercury was chosen as the model liquid metal because it is liquid at room temperature, and so should have negligible temperature gradients beyond those produced in the laser generation process, and because it exhibits a very shallow optical penetration depth. Brief descriptions about the theory of laser generation by thermoelastic and ablation sources at the surface of a liquid metal are included. Both thermoelastic expansion and ablation cause similar ultrasound generation in liquid metals when laser generated ultrasonic pulses are directed perpendicular to the surface of liquid metals. The ultrasonic pulse amplitude is proportional to the absorbed laser pulse energy for both mechanisms. The simple threshold model presented for ablation describes the transition from thermoelastic generation with the model's two parameters being material dependent. For mercury, ablation produces about 100 times larger ultrasonic pulse amplitudes than thermoelastic expansion and has a threshold of about 6 MW/square cm. Molten metals offer a good medium for studying ablation, since the surface is always refreshed and ablation, at least for mercury, dominates ultrasonic generation above the threshold. DOE

EFFECT OF INTERNAL HYDROGEN ON THE MIXED-MODE 1/3 FRACTURE TOUGHNESS OF A FERRIFIC/MARTENSITIC STAINLESS STEEL

Huaxin Li (Associated Western Universities, Inc., Richland, WA.), R. H. Jones, D. S. Gelles, and J. P. Hirth (Washington State Univ., Pullman, WA.) Sep. 1994 10 p Presented at the 5th International Conference on Hydrogen Effects on Material Behavior, Moran, WY, 11-15 Sep. 1994
(Contract DE-AC06-76RL-01830)
(DE95-005722; PNL-SA-24007; CONF-940945-6) Avail: CASI HC A02/MF A01

The effects of H on the mixed-mode 1/3 critical J-integrals (J(sub TC)) and tearing moduli (dJ/da) were examined for a martensitic stainless steel at ambient temperature. A H content of 4 ppm(wt) was attained after charging in a H2 gas chamber (138 MPa) at 300 C for 2 weeks. Results showed that H decreased J(sub TC) and dJ/da values compared to steel tested without H. However, the presence of H did not change the dependence of J(sub TC) and dJ/da values on the crack angles. Both J(sub IC) and dJ(sub 1)/da exhibited the highest relative values. The minimum values of both J(sub TC) and dJ/da occurred at a crack angle between 35 and 55 deg P(sub iii) /(P(sub iii) + P(sub i)) = 0.4 and 0.6. A mechanism of the combined effect of H and mixed-mode on J(sub TC) and dJ/da is discussed. DOE

ENGINEERED MATERIALS FOR APPLIATION IN SEVERE METALLURGICAL ENVIRONMENTS: TANTALUM-CARBON ALLOY DEVELOPMENT

K. M. Axler Feb. 1995 154 p
(Contract W-7405-eng-36)
(DE95-006838; LA-12876-T) Avail: CASI HC A08/MF A02

A suite of investigations has been completed to develop and demonstrate a construction material for use in severely corrosive metallurgical processing environments. The material is a tantalum-base alloy with inclusions of Ta2C. Alloy development work involved multi-step thermal processing to invoke specific microstructural features. The kinetics of carbide formation from supersaturated solid solutions of carbon in tantalum were established. Performance evaluation of the alloy was conducted and the alloy has been demonstrated to outperform any previously studied metallic construction material used in pyrometallurgical processing of plutonium. Specific microstructural features of the alloy have been identified which provide the extreme corrosion resistance. Grain boundary occupancy by the Ta2C phase is associated with the corrosion resistance to liquid metal. Precipitation from the supersaturated condition invokes a microstructure with the most significant grain boundary delineation by carbide inclusions and hence provides the most corrosion resistant attributes. It has been experimentally proven that the precipitate growth rate is not dictated solely by the diffusion rate of the interstitial species and is more complex. The observed growth rate of carbide precipitates involves several competing effects. DOE

RADIATION-INDUCED SEGREGATION: A MICROCHEMICAL GAUGE TO QUANTIFY FUNDAMENTAL DEFECT PARAMETERS

E. P. Simonen and S. M. Bruemmer Dec. 1994 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC06-76RL-01830)
(DE95-005720; PNL-SA-24864; CONF-941144-50) Avail: CASI HC A02/MF A01

Defect Kinetic parameters are evaluated for austenitic stainless alloys by comparing model predictions to measured responses for radiation-induced grain boundary segregation. Heavy-ions, neutrons and proton irradiations having substantial statistical bases are examined. The combined modeling and measurement approach is shown to be useful for quantifying fundamental defect parameters. The mechanism evaluation indicates vacancy migration energies of 1.15 eV or less and a vacancy formation energy at grain boundaries of 1.5 eV. Damage efficiencies of about 0.03 were established for heavy-ions and for light-water reactor neutrons. Inferred proton damage efficiencies were about 0.15. Segregation measured in an advanced gas-cooled reactor component was much greater than expected using the above parameters. DOE

N95-27493# Pacific Northwest Lab., Richland, WA.

RADIATION-INDUCED GRAIN BOUNDARY SEGREGATION IN AUSTENITIC STAINLESS STEELS

S. M. Bruemmer, L. A. Charlot, J. S. Vetrano, and E. P. Simonen Nov. 1994 12 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC06-76RL-01830)
(DE95-005721; PNL-SA-25507; CONF-941144-51) Avail: CASI HC A03/MF A01

Radiation-induced segregation (RIS) to grain boundaries in Fe-Ni-Cr-Si stainless alloys has been measured as a function of irradiation temperature and dose. Heavy-ion irradiation was used to produce damage levels from 1 to 20 displacements per atom (dpa) at temperatures from 175 to 550 C. Measured Fe, Ni, and Cr segregation increased sharply with irradiation

dose (from 0 to 5 dpa) and temperature (from 175 to about 350 C). However, grain boundary concentrations did not change significantly as dose or temperatures were further increased. Although interfacial compositions were similar, the width of radiation-induced enrichment or depletion profiles increased consistently with increasing dose or temperature. Impurity segregation (Si and P) was also measured, but only Si enrichment appeared to be radiation-induced. Grain boundary Si peaked at levels approaching 10 at% after irradiation doses to 10 dpa at an intermediate temperature of 325 C. No evidence of grain boundary silicide precipitation was detected after irradiation at any temperature. Equilibrium segregation of P was measured in the high-P alloys, but interfacial concentration did not increase with irradiation exposure. Comparisons to reported RIS in neutron-irradiated stainless steels revealed similar grain boundary compositional changes for both major alloying and impurity elements.

MATERIALS CONSIDERATIONS FOR MOLTEN SALT ACCELERATOR-BASED PLUTONIUM CONVERSION SYSTEMS
J. H. DeVan, J. R. DiStefano, W. P. Eatherly, J. R. Keiser, and R. L. Klueh 1994 13 p Presented at the International Conference on Accelerator-driven Transmutation Technologies and Applications, Las Vegas, NV, 25-28 Jul 1994
(Contract DE-AC05-84OR-21400)
(DE95-006743; CONF-9407103-34) Avail: CASI HC A03/MF A01

A Molten-Salt Reactor Program for power applications was initiated at the Oak Ridge National Laboratory in 1956. In 1965 the Molten Salt Reactor Experiment (MSRE) went critical and was successfully operated for several years. Operation of the MSRE revealed two deficiencies in the Hastelloy N alloy that had been developed specifically for molten-salt systems. The alloy embrittled at elevated temperatures as a result of exposure to thermal neutrons (radiation damage) and grain boundary embrittlement occurred in materials to fuel salt. Intergranular cracking was found to be associated with fission products, viz. tellurium. An improved Hastelloy N composition was subsequently developed that had better resistance to both of these problems. However, the discovery that fission product cracking could be significantly decreased by making the salt sufficiently reducing offers the prospect of improved compatibility with molten salts containing fission products and resistance to radiation damage in ABC applications. Recommendations are made regarding the types of corrosion tests and mechanistic studies needed to qualify materials for operation with PuF_3-containing molten salts. DOE

CHARACTERIZATION OF DEFECTS IN DEUTERIUM-IMPLANTED BERYLLIUM
R. A. Anderl (Idaho National Engineering Lab., Idaho Falls, ID.), A. B. Denison (Idaho National Engineering Lab., Idaho Falls, ID.), S. Szpala, P. Asoka-Kumar, K. G. Lynn, and B. Nielsen 1994 11 p Presented at the 5th International Conference on Hydrogen Effects on Material Behavior, Moran, WY, 11-15 Sep. 1994
(Contracts DE-AC02-76CH-00016; DE-AC07-94ID-13223)
(DE95-005688; BNL-61143; CONF-940945-5) Avail: CASI HC A03/MF A01

This work investigated surface material modifications in high-purity beryllium foils resulting from 1-keV deuterium ion implantation into specimens for which the anneal temperatures and implantation temperatures were varied. Defects in unimplanted and in deuterium-implanted beryllium were characterized principally by positron-beam depth-profile analyses. Depth-profiles of the defect distributions in the specimens were made by stepping the energy of the positron beam from 0.055 keV to 40 keV, accompanied by measurements of the Doppler-broadened annihilation radiation line shape at each positron energy. These analyses identified a varying defect structure in beryllium, dependent on the previous anneal history of the material and on the temperature of the material during implantation with energetic deuterium ions. For specimens implanted at room temperature with 1-keV/D ions, the beam-induced defect structure had a profile that was peaked near the mean. range of the implanting deuterium and that extended beyond the implantation zone. Isochronal step-thermal anneal experiments revealed that deuterium was released from these defects at a temperature of about 400 k, indicative of shallow traps, and that the defect structure annealed at temperatures above 623 K. The beam-induced vacancy-defect complexes were estimated to be 1-nm voids for 1-keV/D implantation into Be at room temperature. For beryllium implanted at temperatures of 723 K with 1-keV/D ions, these measurements revealed that the beam-induced defect structure was much broader and extended far beyond the implantation zone. Isochronal stepthermal anneal experiments for these specimens revealed a more stable defect structure, with the onset of defect annealing at 775 K. There was no evidence of deuterium release at lower temperatures, indicating that for beryllium implanted at elevated temperatures, deuterium is retained in deep traps.

SYSTEMATIC STUDY OF THE ION BEAM MIXING OF OXIDE MARKERS INTO ALUMINA
Elizabeth A. Cooper, Harriet Kung, and Michael Nastasi 1995 19 p Presented at the 9th International Conference on Ion Beam Modification of Materials, Canberra, Australia, 5-10 Feb. 1995
(Contract W-7405-eng-36)
(DE95-006262; LA-UR-95-208; CONF-950220-2) Avail: CASI HC A03/MF A01

The study of ion beam mixing of layered compositions is important in two regards: first, there is the potential of alloying the layers into a new functionally different composition and, secondly, from a fundamental aspect, it is important be able to anticipate the potential damage due to degradation of the layer structure that could be caused in these materials due to a radiation environment. The authors have completed a systematic study of ion beam mixing of thin marker layers into amorphous alumina. The degree of mixing was found to be controlled by thermodynamic factors, the nature of the marker (oxidation state), and matrix crystallinity. Ballistic mixing was observed for all markers, but the mixing of some oxide markers exhibits a thermally activated regime at higher temperatures. The experiments were conducted from a low temperature of -170 C to a maximum temperature of 75O C. 210 keV Ar was used to ion beam mix the marker layer at the various temperatures. The marker spreading was analyzed using RBS. The mixing of one marker (Fe_2O_3) into crystalline alumina (sapphire) was compared to that of the amorphous alumina. It was found that the marker mixed asymmetrically into the two matrix materials, with a higher degree of mixing into the amorphous matrix. TEM cross-section results verify that there is a preference for the marker to mix into the amorphous alumina layer preferentially to the crystalline layer. The interest in ion beam mixing of marker layers in ceramic systems is motivated by the fact that layered oxides are technologically important materials for fusion reactor applications. DOE

STUDY OF THE PHASE TRANSFORMATIONS AND MICROSTRUCTURES OF URANIUM RICH ALLOYS OF THE BINARY URANIUM-GALLIUM SYSTEM Ph.D. Thesis
David Dayan Jul. 1994 146 p
(DE95-609624; NRCN-605) Avail: CASI HC A07/MF A02 (US Sales Only)

Little data was found on the properties of the binary alloy system of uranium-gallium. Therefore, an extensive investigation of the crystal-phase transformations, crystallography and metallography of this alloy system was carried out. Various experimental techniques were employed. The investigation provided information on the morphology of dilute U(Ga) alloys, on the kinetics and on the mechanism of the crystallography of the martensitic transformation beta-alpha. The main results are: (1) Gallium is soluble in the allotropic tau and beta-uranium phases. (2) The delta-phase corresponds to the stoichiometric U_3Ga_5 compound. (3) Gallium is a beta-stabilizing element similar to chromium. (4) The beta-phase is unstable at room temperature and undergoes ultimately a shear-like transformation into the alpha-U, which itself is a metastable variant of the alpha-U structure. (5) Ultrasonic sound velocity measurements were used to determine the elastic constants, Young, shear and bulk moduli of the polycrystalline beta-stabilized uranium 1.6 at.% Ga and uranium 2.3 at.% Ga alloys between 77 and 300 deg K. (6) Transmission electron microscopy was used to study the crystallography of the martensitic transformation taking place in an U-1.6 at.% Ga alloy. (7) The atomistic model proposed for the beta-alpha transformation in U(Ga) alloy is based on the crystallographic results and the observed low activation energy. (h) The correspondence which describes mathematically the way in which the parent beta-U and the daughter alpha-U phase are related was calculated by the means of an axis transformation using the known lattice parameters and the orientation relationships between the two structures. DOE

PROCESSING AND PROPERTIES OF CHROMATE-FREE CONVERSION COATINGS ON ALUMINUM
R. G. Buchheit, C. A. Drewien, M. A. Martinez, and G. E. Stoner (Virginia Univ., Charlottesville, VA.) 1994 14 p Presented at the Corrosion '95: National Association of Corrosion Engineers (NACE) International Annual Conference and Corrosion Show, Orlando, FL, 26-31 Mar. 1995
(Contract DE-AC04-94AL-85000)
(DE95-004768; SAND-94-3141C; CONF-950304-8) Avail: CASI HC A03/MF A01

A conversion coating method has been developed based on precipitation of Li2(Al2(OH)6)2 center-dot CO3 center-dot 3H2O from alkaline lithium salt solutions. The process is procedurally similar to chromate conversion coating but does not use or produce hazardous chemicals. The coating that forms is polycrystalline, continuous, and conformal. The coating meets the MIL-C-5541E corrosion resistance, electrical contact resistance, and paint adhesion requirements for certain aluminum alloys, but does not match the levels of performance exhibited by chromate conversion coatings. Methods for producing the coating are described. Corrosion resistance has been characterized using electrochemical impedance spectroscopy and salt spray exposure. The structural, compositional, and property changes attending post-coating thermal exposure are discussed. Performance in standardized corrosion, electrical, and paint adhesion tests is also presented. DOE

A NEW Cu-8 Cr-4 Nb ALLOY FOR HIGH TEMPERATURE APPLICATIONS
D. L. Ellis (Case Western Reserve Univ., Cleveland, OH.), G. M. Michal (Case Western Reserve Univ., Cleveland, OH.), and R. L. Dreshfield Jun. 1995 6 p
(Contract NCC3-94; RTOP 242-20-06)
(NASA-TM-106910; E-9612; NAS 1.15:106910) Avail: CASI HC A02/MF A01

Various applications exist where a high conductivity alloy with good strength and creep resistance are required. NASA LeRC has developed a Cu-8 at. percent Cr-4 at. percent Nb (Cu-8 Cr-4 Nb) alloy for these applications. The alloy is designed for use up to 700 C and shows exceptional strength, low cycle fatigue (LCF) resistance, and creep resistance. Cu-8 Cr-4 Nb also has a thermal conductivity of at least 72 percent that of pure Cu. Furthermore, the microstructure and mechanical properties of the alloy are very stable. In addition to the original application in combustion chambers, Cu-8 Cr-4 Nb shows promise for welding electrodes, brazing fixtures, and other applications requiring high conductivity and strength at elevated temperatures. Author

SIMULATIONS OF METAL DISSOLUTION AND CORROSION Final Report, Jan. 1993 - Jun. 1994
P. C. Searson 1995 14 p
(Contract DE-FG02-89ER-45388)
(DE95-007486; DOE/ER-45388/T3) Avail: CASI HC A03/MF A01

There has been considerable interest in microscopic aspects of material removal processes in fields such as corrosion, erosion, evaporation, battery technology, electropolishing, and semiconductor etching. Reports of theoretical work related to many of these problems can be found in the literature although metal dissolution is a noticeable exception. Critical issues common to all dissolution reactions include the relationship between the surface morphology and the driving term (e.g. potential, concentration, temperature); the role of surface active sites, dislocations, and other heterogeneities to the dissolution kinetics; and the influence of surface diffusion. We have shown that microscopic analysis of electrochemically dissolving metal surfaces via computer simulations can lead to a fundamental understanding of the relationship between surface morphology and dissolution kinetics. Microscopic information on surface processes is not contained in phenomenological equations such as the Butler-Volmer equation, which is commonly used to describe electrode dissolution. In particular, we find that the surface roughness and, consequently, the number of surface active sites, are determined by thermodynamic parameters such as the applied electrode potential. The morphology of surfaces has been shown to be an essential aspect of kinetic processes such as crystal growth and mineral dissolution. Electrochemical processes, however, are fundamentally different in that they feature the presence of very high electrical fields at the interface, which directly affect the surface reactions. To date, treatments of the kinetics of electrochemically dissolving metal surfaces have ignored surface morphology. Over the next few years, results from theoretical modeling of dissolution processes, in conjunction with new experimental techniques such as STM, are expected to provide a new insight into the processes controlling metal dissolution and corrosion. PARTICLE-LIKE ABSORPTION SPECTRA IN SMALL TRANSITION METAL CLUSTERS
M. B. Knickelbein 1995 5 p
(Contract W-31-109-eng-38)
(DE95-007082; ANL/CHM/PP-80412) Avail: CASI HC A01/MF A01

Research at Argonne has found that small clusters of certain transition metal atoms display optical absorption spectra that are fundamentally different from those typically observed for other small molecules. A new laser technique known as photodissociation spectroscopy was used to record the absorption spectra of nickel clusters containing three to seven atoms and of niobium clusters containing between seven and twenty atoms. Instead of displaying spectra with distinct and separate absorption 'bands' as is usually seen for small molecules, these metal clusters possess absorption spectra that are continuous and smooth throughout the visible and near ultraviolet regions, indicating that they absorb light at every wavelength. This behavior is in fact more like that displayed by much larger metal particles containing hundreds or thousands of atoms. This surprising result may indicate that the electronic structures of these small clusters are much closer to those of a corresponding macroscopic piece of nickel or niobium metal than was previously thought. These studies are aimed at understanding the electronic structure of the active metal cluster sites in catalysts, and may in addition provide valuable insights into the design and properties of new cluster assembled materials. A FIRST PRINCIPLES APPROACH TO PHASE STABILITY AND ORDER-DISORDER TRANSFORMATION: APPLICATION TO LI-AI ALLOYS
Ashok Arya, Srikumar Banerjee (Bhabha Atomic Research Centre, Bombay, India.), and Gour P. Das Aug. 1994 36 p
(DE95-609152; IC-94/242) Avail: CASI HC A03/MF A01 (US Sales Only)

Starting from TB-LMTO electronic structure total energy calculations of ordered binary alloys, we have determined the configurationally averaged effective (multisite) cluster interactions (ECI's) using the Connolly-Williams inversion method. The configurational entropy has been calculated in the mean field approximation of the Ising model using the cluster variation method (CVM). The resulting configurational free energy (or equivalently the grand potential) has been minimized and order-disordered transformation behavior in Li-Al alloys has been discussed. DOE

CROSSOVER INTEGRAL EQUATION THEORY FOR THE LIQUID STRUCTURE STUDY
S. K. Lai and H. C. Chen (National Central Univ., Chung-Li, Taiwan.) Aug. 1994 13 p
(DE95-609155; IC-94/252) Avail: CASI HC A03/MF A01 (US Sales Only)

The main purpose is to report on a calculation that describes the role of the long-range bridge function as applied to the study of structure of simple liquid metals. It was found here that this bridge function accounts pretty well for the major part of long-range interactions but is physically inadequate for describing the short-range part of liquid structure. To improve on the theory we have drawn attention to the crossover integral equation method which, in essence, amounts to adding to the above bridge function a short-range correction of bridge diagrams. The suggested crossover procedure has been tested for the case of liquid metal Cs. Remarkably good agreement with experiment was obtained confirming our conjecture that the crossover integral equation approach as stressed in this work is potentially an appropriate theory for an accurate study of liquid structure possibly for the supercooled liquid regime. ELECTRONIC STRUCTURE OF DISORDERED Cu-Ag ALLOYS
S. S. A. Razee Aug. 1994 11 p
(DE95-609156; IC-94/258) Avail: CASI HC A03/MF A01 (US Sales Only)

We present a self-consistent-field Korringa-Kohn-Rostoker coherent potential approximation study of the electronic structure of disordered Cu(x)Ag(1-x) alloys for x = 0.0, 0.25, 0.50, 0.75, and 1.0. In particular, we focus on the Fermi surface, density of states, and Bloch spectral density, and study how they evolve as a function of x. We find that Fermi surface dimensions have a nonlinear composition dependence. The disorder-induced smearing of the Fermi surface, as expected, is very high along the zone axes (111) direction; both the Cu and Ag Fermi surfaces have a neck in this direction. Whenever possible we have compared our results with the available experimental data. DOE

FORMING METALLURGY: SUPERVISED DRAWING COURSE, NTH
T. Iveland 1994 104 p Prepared in cooperation with Technical Univ. of Norway, Trondheim
(PB95-196507; STF24-A94510) Avail: Issuing Activity (National Technical Information Service (NTIS))

A short introduction of texture and deformation models of polycrystalline metals is given. Work hardening based on dislocation theory and the effect of factors such as strain rate and temperature are also discussed. Some useful empirical relations between stress and strain are presented, and the size and shape of the yield surface during plastic deformation is described by continuum mechanics equations. Some of the most common test methods used to determine the formability of metallic materials are presented. Examples of such methods are the tension, the compression, and the torsion test. A brief presentation of common plastic forming processes along with some approximate methods to decide the necessary deformation force and the flow pattern during the forming operations are given. Finally, simplified analysis methods are applied on forming processes by using some of these simplified methods and a brief view of the possibilities using finite element methods in bending operations is presented. FIRST-PRINCIPLES CALCULATIONS FOR AlN, GaN, AND InN: BULK AND ALLOY PROPERTIES
A. F. Wright and J. S. Nelson 1995 17 p
(Contract DE-AC04-94AL-85000)
(DE95-006822; SAND-95-0144C) Avail: CASI HC A03/MF A01

First-principles density-functional calculations utilizing ab initio pseudopotentials and plane-wave expansions are used to determine lattice parameters, bulk moduli, and band structures for AlN, GaN, and InN. It is found that large numbers of plane waves are necessary to resolve the nitrogen 2p wave functions and that explicit treatment of the gallium 3d and indium 4d electrons is important for an accurate description of GaN and InN. Several properties of ternary zinc-blende alloys are determined including their bond-length and bond-angle relaxation and their energy-gap bowing parameters. The similarity of the calculated zinc-blende and wurtzite direct gaps also allows estimates to be made of the energy gap versus composition for wurtzite alloys. DOE

EFFECTS OF HYDROGEN ON CARBON STEELS AT THE MULTI-FUNCTION WASTE TANK FACILITY
W. C. Carlos Feb. 1995 29 p
(Contract DE-AC06-87RL-10930)
(DE95-007194; WHC-SD-W236A-ES-004) Avail: CASI HC A03/MF A01

Concern has been expressed that hydrogen produced by corrosion, radiolysis, and decomposition of the waste could cause embrittlement of the carbon steel waste tanks at Hanford. The concern centers on the supposition that the hydrogen evolved in many of the existing tanks might penetrate the steel wall of the tank and cause embrittlement that might lead to catastrophic failure. This document reviews literature on the effects of hydrogen on the carbon steel proposed for use in the Multi-Function Waste Tank Facility for the time periods before and during construction as well as for the operational life of the tanks. The document draws several conclusions about these effects. Molecular hydrogen is not a concern because it is not capable of entering the steel tank wall. Nascent hydrogen produced by corrosion reactions will not embrittle the steel because the mild steel used in tank construction is not hard enough to be susceptible to hydrogen stress cracking and the corrosion product hydrogen is not produced at a rate sufficient to cause either loss in tensile ductility or blistering. If the steel intended for use in the tanks is produced to current technology, fabricated in accordance with good construction practice, postweld heat treated, and operated within the operating limits defined, hydrogen will not adversely affect the carbon steel tanks during their 50-year design life. PHASE STABILITY AND ELASTICITY OF C15 TRANSITION-METAL INTERMETALLIC COMPOUNDS
F. Chu, T. E. Mitchell, S. P. Chen, M. Sob (Pennsylvania Univ., Philadelphia, PA.), R. Siegl (Pennsylvania Univ., Philadelphia, PA.), and D. P. Pope (Pennsylvania Univ., Philadelphia, PA.) 1995 12 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society, Las Vegas, NV, 12-16 Feb. 1995
(Contract W-7405-eng-36)
(DE95-007876; LA-UR-95-473; CONF-950201-6) Avail: CASI HC A03/MF A01

First-principle quantum mechanical calculations based on the local-density-functional theory have been performed to study the electronic, physical and metallurgical properties of C15 intermetallics MV2 (M = Zr, Hf, or Ta). The elastic constants of C15 HfV2 + Nb were measured by the resonant ultrasound spectroscopy technique. The phase stability of C15 HfV2 + Nb was studied by specific heat measurements and by transmission electron microscopy in a low temperature specimen holder. The total energies and their lattice volume dependence were used to obtain the equilibrium lattice constants and bulk modulus. The band structures at the X-point near the Fermi level were employed to understand the anomalous temperature dependence of shear modulus of the C15 intermetallics. It was found that the double degeneracy with a linear dispersion relation of electronic levels at the X-point near the Fermi surface is mainly responsible for the C15 anomalous elasticity. The density of states at the Fermi level, N(E(sub F)), and the Fermi surface geometry were obtained to understand the low temperature phase instability of C15 HfV2 and ZrV2 and the stability of C15 TaV2. It was proposed that the large N(E(sub F)) and Fermi surface nesting are the physical reasons for the structural instability of the C15 HfV2 and ZrV2 at low temperatures. The relation between anomalous elasticity and structural instability of C15 HfV2 and ZrV2 is also discussed. DOE

BETA-DYNAMICS IN SIMPLE LIQUID METAL
S. K. Lai Aug. 1994 24 p
(DE95-609154; IC-94/247) Avail: CASI HC A03/MF A01 (US Sales Only)

The modified hypernetted chain theory is applied to calculate the static liquid structure factor for simple liquid metals at rapid cooling. With a proper choice of bridge function, it is found that this integral equation theory is capable of yielding reasonably accurate liquid structure factor in the supercooled liquid region. To exploit the usefulness of the calculated liquid structure, we combine these structure data with the mode-coupling theory to investigate the dynamics of the (beta)-process. It is demonstrated in this work that the critical temperature for an ideal glass transition predicted here for liquid metals Na and K are slightly lower than those determined previously using computer simulated structure factors. In particular, we show that the material-dependent exponent parameter (lambda) which is used widely in the literature as a fitting parameter in the analysis of light scattering experiments can be given more physical significance if one correlates the change of (lambda) with the microscopic interaction or particles specifically for the liquid metal, Lennard-Jones fluid and hard-sphere system. The implication of the present results and the possibility to extract useful information for more complicated systems will be discussed in the text. DOE

EFFECTS OF INTERLAYERS ON THE SCRATCH ADHESION PERFORMANCE OF ULTRA-THIN FILMS OF COPPER AND GOLD ON SILICON SUBSTRATES
S. D. McAdams, T. Y. Tsui, G. M. Pharr (Rice Univ., Houston, TX.), and W. C. Oliver (Nano Instruments, Inc., Knoxville, TN.) 1995 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE95-007367; CONF-941144-68) Avail: CASI HC A02/MF A01

Scratch testing has long been used to assess the adhesion of a film to its substrate. As film thicknesses have decreased, the need for greater precision and sensitivity in the scratch testing apparatus has increased. To this end, a nanoindenter was modified to make finely controlled, low-load scratches. Scratches at various loads and two orientations of a Berkovich scratching diamond were made in films of 100 nm of gold and 200 nm of copper, each on single crystal silicon. For each film type, samples with no interlayer, with an SiO2 interlayer, and with a TiW on SiO2 interlayer were tested. The scratch morphology was found to vary in a regular way with load, diamond orientation and interlayer material. DOE

TRACE ELEMENTS AND THE MECHANICAL PROPERTIES OF INTERMETALLIC COMPOUNDS
Hui Lin (Pennsylvania Univ., Philadelphia, PA.), D. P. Pope (Pennsylvania Univ., Philadelphia, PA.), and E. P. George 1995 41 p Presented at the International Conference on Ultrahigh Purity Metals, Sendai, Japan, 23-27 May 1994
(Contract DE-AC05-84OR-21400)
(DE95-007378; CONF-9405290-1) Avail: CASI HC A03/MF A01

In this paper the brittleness of grain boundaries in Ni3Al is discussed with special emphasis on the effects of B. The effects of alloy stoichiometry, environment (hydrogen), grain boundary character and B levels are described and interpreted in terms of current theories. It is shown that the grain boundaries in Ni3Al are intrinsically weaker than the bulk (the weakness is not an impurity effect), the weakness is exacerbated by atmospheric moisture, and that B in the boundaries both increases the intrinsic strength of the boundaries and reduces the deleterious effects of atmospheric moisture. Only low angle boundaries and twin boundaries are intrinsically strong in Ni3Al, even in the absence of B. DOE

DEFECT CHARACTERIZATION OF ELECTRONIC CONDUCTING PSEUDO-PEROVSKITE SYSTEMS Final Report
H. U. Anderson, M. Nasrallah, D. M. Sparlin, and P. E. Parris 1994 19 p
(Contract DE-FG02-85ER-45219)
(DE95-007487; DOE/ER-45219/T3) Avail: CASI HC A03/MF A01

The goal of the program has been to study the interrelationships between electrical conductivity, oxidation-reduction kinetics, defect structure, and composition of n- and p-type binary and ternary transition metal oxides. The stimulus for making these studies was the observation that both conducting n- and p-type oxides displayed a dependence on oxygen activity that was not predicted by the defect chemistry of their majority defects. The project has focused primarily on the understanding of electronic and ionic conduction in the REBO3 oxides, where RE is a rare earth ion and B is a transition metal ion. This is being done by studying the interrelationships between the electronic and ionic conductivity, the electronic structure of the B site transition metal ion, and the acceptor concentration. The dependence of these characteristics on the oxygen activity, the temperature, and the defect chemistry of the oxide system is being determined. Theoretical mechanisms and models are being developed from the body of experimental results to provide a predictive tool. The effect of dopants and impurities, processing, electrical and thermal stability as a function of oxygen activity and temperature and their relationship to defect chemistry of the perovskite type oxides have been studied extensively by this research team. As a result of the difference in mobility between electronic and ionic defects, the electrical conductivity changes as the concentration of electronic defects changes. Thus, electrodes or resistors consisting of such oxides are susceptible to instabilities in resistance as they are cycled into temperature regimes where thermodynamic equilibrium may be attained. Many of the new energy conversion systems which use such oxides are encountering difficulties as a result of this instability in resistivity. DOE

GAMMA RAY-INDUCED EMBRITTLEMENT OF PRESSURE VESSEL ALLOYS
D. E. Alexander, L. E. Rehn, K. Farrell (Oak Ridge National Lab., TN.), and R. E. Stoller (Oak Ridge National Lab., TN.) Nov. 1994 9 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-31-109-eng-38)
(DE95-007133; ANL/MSD/CP-83383; CONF-941144-72) Avail: CASI HC A02/MF A01

High-energy gamma rays emitted from the core of a nuclear reactor produce displacement damage in the reactor pressure vessel (RPV). The contribution of gamma damage to RPV embrittlement has in the past been largely ignored. However, in certain reactor designs the gamma flux at the RPV is sufficiently large that its contribution to displacement damage can be substantial. For example, gamma rays have been implicated in the accelerated RPV embrittlement observed in the High Flux Isotope Reactor (HFIR) at Oak Ridge National Laboratory. In the present study, mechanical property changes induced by 10-MeV electron irradiation of a model Fe alloy and an RPV alloy of interest to the HFIR were examined. Mini-tensile specimens were irradiated with high-energy electrons to reproduce damage characteristic of the Compton recoil-electrons induced by gamma bombardment. Substantial increases in yield and ultimate stress were observed in the alloys after irradiation to doses up to 5.3x10(exp -3) dpa at temperatures (approximately 50 C) characteristic of the HFIR pressure vessel. These measured increases were similar to those previously obtained following neutron irradiation, despite the highly disparate nature of the damage generated during electron and neutron irradiation. DOE

HIGH TEMPERATURE HEXOLOY(TRADEMARK) SX SILICON CARBIDE Final Report
G. V. Srinivasan, S. K. Lau, and R. S. Storm Sep. 1994 98 p Prepared in cooperation with Carborundum Co., Nia gara Falls, NY Sponsored by Martin Marietta Energy Systems, Inc.
(Contract DE-AC05-84OR-21400)
(DE95-007290; ORNL/Sub-91-SG341/1) Avail: CASI HC A05/MF A02

HEXOLOY(reg sign) SX-SiC, fabricated with Y and Al containing compounds as sintering aids, has been shown to possess significantly improved strength and toughness over HEXOLOY(reg sign)SA-SiC. This study was undertaken to establish and benchmark the complete mechanical property database of a first generation material, followed by a process optimization task to further improve the properties. Mechanical characterization on the first generation material indicated that silicon-rich pools, presumably formed as a reaction product during sintering, controlled the strength from room temperature to 1,232 C. At 1,370 C in air, the material was failing due to a glass-phase formation at the surface. This glass-phase formation was attributed to the reaction of yttrium aluminates, which exist as a second phase in the material, with the ambient. This process was determined to be a time-dependent one that leads to slow crack growth. Fatigue experiments clearly indicated that the slow crack growth driven by the reaction occurred only at temperatures greater than 1,300 C, above the melting point of the glass phase. Process optimization tasks conducted included the selection of the best SiC powder source, studies on mixing/milling conditions for SiC powder with the sintering aids, and a designed experiment involving a range of sintering and post-treatment conditions. The optimization study conducted on the densification variables indicated that lower sintering temperatures and higher post-treatment pressures reduce the Si-rich pool formation, thereby improving the room-temperature strength. In addition, it was also determined that furnacing configuration and atmosphere were critical in controlling the Si-rich formation. DOE

THE EFFECTS OF PROCESSING VARIABLES ON REACTION SYNTHESIS OF Fe-Al ALLOYS
D. L. Joslin, D. S. Easton, C. T. Liu, and S. A. David 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007405; CONF-941144-75) Avail: CASI HC A02/MF A01

The effects of alloy composition and reaction atmosphere on reaction synthesis of binary FeAl alloys were studied. Reactions were observed in an open (air) furnace, under static vacuum (in an evacuated quartz tube) and in a dynamic vacuum furnace. High-speed videotapes of reaction syntheses of compacts formed from 45 micrometer Fe and 10 micrometer Al powders reacted in air and under static vacuum revealed that an unusual 'two-stage' reaction exists in this system under these conditions. The first stage of the two-stage reaction lasts several seconds and starts at around 650 C. The second stage begins at about 900 C, reaching temperatures between 1,250 and 1,350 C. The progress of the reaction to the second stage is sensitive to the alloy composition and reaction environment. The reaction behavior is explained in terms of thermodynamics and heat transfer, which control the delicate balance between beat accumulation and heat loss during reaction synthesis. DOE

IMPROVED HARDNESS RHA WELDABILITY AND MATERIAL PROPERTY TESTING Final Technical Report, Aug. 1991 - Jun. 1994
Michael L. Foos Dec. 1994 126 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL04-91-C-0040)
(AD-A289127) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The M1-PMO, in conjunction with the US Army Research Laboratory (ARL) would like to potentially up-armor the M1 family of vehicles by increasing the hardness of rolled homogeneous armor (RHA) MIL-A-12560 steel. The basic thrust of the program is to utilize lower tempering temperatures and chemistries of slightly more hardenability to produce a RHA armor with a Rockwell 'C' hardness of 39-48 without altering the current specification MIL-A-12560 steel. It is believed that the increased hardness levels will provide increased ballistic protection against large caliber kinetic energy threats. Weldability and material property tests were performed on the improved hardness RHA steel supply by the US ARL. The program involves basic material characterization, weldability, machinability and plate cutting studies. The material characterization was performed on two thicknesses (1.25' and 1.50'). The weldability study included Y-groove preheat testing, stud welding and maximum heat input testing. The machinability testing involved machining parts including drilling, tapping, reaming, boring and milling. Plasma and Oxy-fuel thermal cutting were studied to gauge processing of the steel by present armor vehicle fabrication. The ballistic testing was performed by US Combat Systems Test Activity (CSTA) at Aberdeen, MD. The results show the candidate steel can processed typical to RHA steel with minor impact to welding and machining. DTIC

PULSED ION BEAM SURFACE TREATMENT FOR PREPARING RAPIDLY SOLIDIFIED CORROSION RESISTANT STEEL AND ALUMINUM SURFACES
R. G. Buchheit, L. M. Maestas, D. C. McIntyre, R. W. Stinnett, and J. B. Greenly (Cornell Univ., Ithaca, NY.) 1995 10 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society, Las Vegas, NV, 12-16 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-007741; SAND-95-0281C; CONF-950201-5) Avail: CASI HC A02/MF A01

Intense, pulsed ion beams were used to melt and rapidly resolidify Types 316F, 316L, and sensitized 304 stainless steel surfaces to eliminate the negative effects of microstructural heterogeneity on localized corrosion resistance. Anodic polarization curves determined for 316F and 316L showed that passive current densities were reduced and pitting potentials were increased due to ion beam treatment. Type 304 samples sensitized at 600 C for 100 h showed no evidence of grain boundary attack when surfaces were ion beam treated. Equivalent ion beam treatments were conducted with a 6061-T6 aluminum alloy. Electrochemical impedance experiments conducted with this alloy exposed to an aerated chloride solution showed that the onset of pitting was delayed compared to untreated control samples. DOE

TOWARD A MECHANISTIC UNDERSTANDING OF RADIATION EFFECTS IN MATERIALS
J. E. Pawel, E. E. Bloom, L. K. Mansur, A. F. Rowcliffe, S. J. Zinkle, R. E. Stoller, and P. J. Maziasz 1995 3 p Presented at the Ishino Conference, Tokyo, Japan, 15-16 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-006530; CONF-941258-1) Avail: CASI HC A01/MF A01

Substantial progress has been made to understanding radiation effects in materials, and in formulating and testing a metallurgical approach for developing radiation-resistant alloys. This understanding is a combination of theoretical modeling with experiments using mixed spectrum fission reactors, fast reactors and ion irradiations. The development of materials with properties to meet the challenges of advanced reactors has four major steps: (1) the development of a mechanistic understanding of the behavior of materials during irradiation in appropriate environments; (2) selection of candidate materials based on physical, chemical, and mechanical properties; (3) development of these candidate materials through compositional and microstructural control to achieve the necessary properties and radiation damage resistance; and (4) the development of a database sufficient to support engineering design, performance analysis, and safety assessment. This paper will present a brief overview of the present understanding of radiation effects in materials, with emphasis on work performed at Oak Ridge National Laboratory as part of the U.S. fusion materials and basic energy sciences programs. Progress in fundamental understanding of void swelling, phase formation and stability, irradiation creep, and post-irradiation mechanical properties has been gained through comparison of experimental data with the predictions of theoretical models.

Applications of the understanding of radiation effects in materials have led to the development of candidate structural materials for use in aggressive radiation environments such as fast breeder reactors and proposed fusion energy systems. Because of the successes associated with the development of radiation resistant austenitic stainless steels, it is believed that these principles will provide the basis for addressing radiation issues in a variety of materials systems. DOE

BASES FOR EXTRAPOLATING MATERIALS DURABILITY IN FUEL STORAGE POOLS
A. B. Johnson, Jr. Dec. 1994 7 p Presented at the Spent Nuclear Fuel Meeting: Challenges and Initiatives, Salt Lake City, UT, 14-16 Dec. 1994
(Contract DE-AC06-76RL-01830)
(DE95-007746; PNL-SA-24126; CONF-941207-25) Avail: CASI HC A02/MF A01

A major body of evidence indicates that zirconium alloys have the most consistent and reliable durability in wet storage, justifying projections of safe wet storage greater than 50 y. Aluminum alloys have the widest range of durabilities in wet storage; systematic control and monitoring of water chemistry have resulted in low corrosion rates for more than two decades on some fuels and components. However, cladding failures have occurred in a few months when important parameters were not controlled. Stainless steel is extremely durable when stress, metallurgical and water chemistry factors are controlled. LWR SS cladding has survived for 25 y in wet storage. However, sensitized, stressed SS fuels and components have seriously degraded in fuel storage pools (FSP's) at approximately 30 C. Satisfactory durability of fuel assembly and FSP component materials in extended wet storage requires investments in water quality management and surveillance, including chemical and biological factors. The key aspect of the study is to provide storage facility operators and other decision makers a basis to judge the durability of a given fuel type in wet storage as a prelude to basing other fuel management plans (e.g. dry storage) if wet storage will not be satisfactory through the expected period of interim storage. SOLID-STATE SINTERING OF TUNGSTEN HEAVY ALLOYS
W. E. Gurwell Oct. 1994 11 p Presented at the 1994 International Conference on Tungsten and Refractory Metals, McLean, VA, 17-19 Oct. 1994
(Contract DE-AC06-76RL-01830)
(DE95-007749; PNL-SA-24841; CONF-9410213-5) Avail: CASI HC A03/MF A01

Solid-state sintering is a technologically important step in the fabrication of tungsten heavy alloys. This work addresses practical variables affecting the sinterability: powder particle size, powder mixing, and sintering temperature and time. Compositions containing 1 to 10 micrometer ((mu)M) tungsten (W) powders can be fully densified at temperatures near the matrix solidus. Blending with an intensifier bar provided good dispersion of elemental powders and good as-sintered mechanical properties under adequate sintering conditions. Additional ball milling increases powder bulk density which primarily benefits mold and die filling. Although fine, 1 (mu)m W powder blends have high sinterability, higher as-sintered ductilities are reached in shorter sintering times with coarser, 5 (mu)m W powder blends; 10(mu)m W powder blends promise the highest as-sintered ductilities due to their coarse microstructural W. THE ROLE OF HYDROGEN IN THE HYDROGENATION AND HYDROGENOLYSIS OF ANILINE ON THE NICKEL SINGLE CRYSTAL SURFACES: ITS IMPLICATION ON THE MECHANISMS OF HDN REACTIONS
S. X. Huang, J. L. Gland, and D. A. Fischer (National Inst. of Standards and Technology, Gaithersburg, MD.) 1995 13 p Presented at the 2nd International Symposium on Advances in Hydrotreating Catalysts, Washington, DC, 22-26 Aug. 1994
(Contract DE-FG02-91ER-14190)
(DE95-006687; CONF-9408210-1) Avail: CASI HC A03/MF A01

The selectivity of hydrogenation and hydrogenolysis reactions for organonitrogen compounds on transition metal surfaces depends heavily on the availability of surface hydrogen under reaction conditions. The surface hydrogen produced during dehydrogenation of adsorbed aniline upon thermal activation does not significantly modify hydrogenolysis reactions because it desorbs below the reaction temperatures. A series of experiments which use external hydrogen to control the concentration of surface hydrogen at reaction temperatures are reported here. In situ kinetic measurements in the presence of reactive hydrogen environments have been used to probe the details of the adsorbed species and reaction mechanisms. Nickel single crystals have been used as well defined model catalysts for hydrodenitrogenation (HDN) reactions. Previously, the effect of external hydrogen on aniline hydrogenolysis on the Pt(111) surface has been reported. On Pt(111), C-N bond activation is substantially enhanced in the presence of hydrogen. The increased C-N bond cleavage is facilitated by hydrogen which maintains a parallel adsorption of the aromatic derivative of aniline. In the absence of surface hydrogen, the adsorbed intermediate tilts away from surface because of partial dehydrogenation with increasing temperature at about 400 K. This paper will discuss a recent study of aniline reactions on the Ni(100) and Ni(111) surfaces both in the presence and absence of hydrogen. Reactivity comparisons will also be made for these two nickel surfaces towards adsorbed aniline. DOE

ACCURACY ISSUES IN MODELING SUPERPLASTIC METAL FORMING
K. I. Johnson, M. A. Khaleel, C. A. Lavender, and M. T. Smith Feb. 1995 17 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society, Las Vegas, NV, 12-16 Feb. 1995
(Contract DE-AC06-76RL-01830)
(DE95-008934; PNL-SA-24828; CONF-950201-8) Avail: CASI HC A03/MF A01

The utility of finite element modeling in optimizing superplastic metal forming is dependent on accurate representation of the material constitutive behavior and the frictional response of the sheet against the die surface. This paper presents work conducted to estimate the level of precision that is necessary in constitutive relations for finite element analysis to accurately predict the deformation history of actual SPF components. Previous work identified errors in SPF testing methods that use short tensile specimens with gauge length-to-width ratios of 2:1 or less. The analysis of the present paper was performed to estimate the error in predicted stress that results from using the short specimens. Stress correction factors were developed and an improved constitutive relation was implemented in the MARC finite element code to simulate the forming of a long, rectangular tray. The coefficient of friction in a Coulomb friction model was adjusted to reproduce the amount of material draw-in observed in the forming experiments. Comparisons between the finite element predictions and the forming experiments are presented. DOE

PRECURSOR PHENOMENON OF MARTENSITIC TRANSFORMATION IN Au-49.5AT%Cd ALLOY
Takuya Ohba (Teikyo Univ., Utsunomiya, Japan.), S. M. Shapiro, Shingo Aoki (Tsukuba Univ., Ibaraki, Japan.), and Kazuhiro Otsuka (Tsukuba Univ., Ibaraki, Japan.) 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC02-76CH-00016)
(DE95-007698; BNL-61391; CONF-941144-66) Avail: CASI HC A02/MF A01

Phonon softening was observed in the parent phase of a AuCd alloy which transforms from the beta(sub 2)(B2) parent to zeta'(sub 2) (trigonal) martensitic. Since Cd strongly absorbs neutrons, the isotope Cd-114 was used in preparing the single crystal for the measurements. The (zeta zeta 0)TA(sub 2) phonon branch was measured and found to be anomalously low. A minimum is present at zeta = 0.35 which softens with decreasing temperature towards Ms. The results are consistent with the model proposed by Ohba et al. based upon a crystallographic study of the zeta'(sub 2) phase. Inst., Naka, Japan.), and M. Nishi (Japan Atomic Energy Research Inst., Naka, Japan.) 13 Oct. 1994 6 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract W-7405-eng-48)
(DE95-007965; UCRL-JC-116967; CONF-941013-27) Avail: CASI HC A02/MF A01

The Fusion ENgineering International eXperiments (FENIX) Test Facility recently has successfully completed the testing of a pair of Nb3Sn cable-in-conduit conductors developed by the Japan Atomic Energy Research Institute. These conductors, made of bronze-processed strands, were designed to operate stably with 40-kA transport current at a magnetic field of 13 T. In addition to the measurements of major design parameters such as current-sharing temperature, FENIX provided several experiments specifically designed to provide results urgently needed by magnet designers. Performed experiments include measurements of ramp-rate limit, current-distribution, stability, and joint performance. This paper presents the design and results of these special experiments. DOE

THE HIGH STRAIN RATE DEFORMATION OF TUNGSTEN SINGLE CRYSTALS Final Report, Aug. 1992 - Apr. 1994
Edward J. Horwath Nov. 1994 66 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1L1-62618-AH-80)
(AD-A288874; ARL-TR-620) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Samples of single-crystal tungsten, in three orientations (100, 110, 111), were compressively deformed at high strain rates (1,000-2,000 /s) using a Kolsky (split-Hopkinson) type pressure bar apparatus. Samples of the single-crystal tungsten were also deformed at low strain rate (0.0001/s) using a conventional load frame. The 110 orientation exhibited constraint of flow consistent with twofold crystal symmetry about this axis, resulting in skewed flow and noncylindrical specimens after the Kolsky bar test. Both the 111 and 110 orientations exhibited a yield or load drop phenomenon. This load drop may have been associated with either: (1) lack of screw dislocation cross slip at high strain rate; (2) twinning of the crystal lattice; or (3) interstitial solute atoms such as nitrogen or carbon pinning dislocations. As a result of this load drop for the lower symmetry 111 and 110 orientations, the quasi-static (0.0001/s) test had higher flow stress for a given strain than the higher strain rate tests with the Kolsky bar. The 100 orientation crystals exhibited uniform deformation and high rate of work-hardening at both low and high strain rates. The unique behavior of these crystals is postulated in terms of the crystal symmetry, structural evolution at various strain rates, and dislocation flow mechanisms. DTIC

REACTOR PRESSURE VESSEL STRUCTURAL INTEGRITY RESEARCH
W. E. Pennell and W. R. Corwin 1994 17 p Presented at the 22nd Transactions of the Water Reactor Safety Information Meeting, Bethesda, MD, 24-26 Oct. 1994 Sponsored in part by Martin Marietta Energy Systems, Inc.
(Contracts DE-AC05-84OR-21400; NRC-1886-8011-9B; NRC-1886-8109-8L)
(DE95-007034; CONF-9410216-10) Avail: CASI HC A03/MF A01

Development continues on the technology used to assess the safety of irradiation-embrittled nuclear reactor pressure vessels (RPV's) containing flaws. Fracture mechanics tests on RPV steel, coupled with detailed elastic-plastic finite-element analyses of the crack-tip stress fields, have shown that (1) constraint relaxation at the crack tip of shallow surface flaws results in increased data scatter but no increase in the lower-bound fracture toughness; (2) the nil ductility temperature (NDT) performs better than the reference temperature for nil ductility transition (RT(sub NDT)) as a normalizing parameter for shallow-flaw fracture toughness data; (3) biaxial loading can reduce the shallow-flaw fracture toughness; (4) stress-based dual-parameter fracture toughness correlations cannot predict the effect of biaxial loading on shallow-flaw fracture toughness because in-plane stresses at the crack tip are not influenced by biaxial loading; and (5) an implicit strain-based dual-parameter fracture toughness correlation can predict the effect of biaxial loading on shallow-flaw fracture toughness. Experimental irradiation investigations have shown that (1) the irradiation-induced shift in Charpy V-notch vs temperature behavior may not be adequate to conservatively assess fracture toughness shifts due to embrittlement, and (2) the wide global variations of initial chemistry and fracture properties of a nominally uniform material within a pressure vessel may confound accurate integrity assessments that require baseline properties. Nanocrystalline Pd and Cu, prepared by inert gas condensation and warm compaction, were studied using x-ray diffraction techniques. A sample of Cu with sub-micrometer grain size produced by severe plastic deformation was also examined. The Warren-Averbach technique was used to separate the line broadening due to grain size, root-mean-squared strain, and faults. Peak shifts and asymmetry were used to determine the long range surface stresses, stacking fault probability, and twin probability. The Young's modulus of a Pd sample was determined by an ultrasonic technique, and compared with the coarse-grained, fully-dense value. DOE

Be is a 'marginal metal'. The stable phase, hcp-Be, has a low Fermi-level density of states and very anisotropic structural and elastic properties, similar to a semiconductor's. At the Be(0001) surface, surface states drastically increase the Fermi-level density of states. The different nature of bonding in bulk-Be and at the Be(0001) surface explains the large outward relaxation. The presence of surface states causes large surface core-level shifts by inducing a higher electrostatic potential in the surface layers and by improving the screening at the surface. The authors experimental and theoretical investigations of atomic vibrations at the Be(0001) surface demonstrate clearly that Be screening of atomic motion by the surface states makes the surface phonon dispersion fundamentally different from that of the bulk. Properties of Be(0001) are so different from those of the bulk that the surface can be considered a new 'phase' of beryllium with unique electronic and structural characteristics. For comparison they also study Be(11'20), a very open surface without important surface states. Be(11'20) is the only clean s-p metal surface known to reconstruct (1 x 3 missing row reconstruction). (PB95-195566; TKK-V-B97) Avail: CASI HC A03

Only a limited number of studies have been published on the oxidation behavior of Ni-concentrate. In the report a brief literature review of both suspension and ignition temperature experiments is presented. In the experimental part of the study, the behavior of a nickel concentrate was investigated in a laminar flow furnace under simulated flash smelting conditions. Sulfur removal from the Ni-concentrate was found to accelerate with increasing gas preheating temperature and/or oxygen content of the reaction gas. Particle size had a noticeable effect on the sulfur removal only at low experimental temperatures and O2-contents. NTIS

CREEP RECOVERY OF PVC AND POLYPROPYLENE
B. E. Read and P. E. Tomlins Dec. 1994 33 p See also PB94-105079
(PB95-185112; NPL-DMM(A)-151) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

Tensile creep and recovery data have been obtained for PVC and polypropylene at 23 C for different age states, creep durations and stress levels. The recovery behavior has been analyzed by a superposition procedure involving an extension to our model for nonlinear creep and different assumptions regarding possible variations in retardation time during the recovery. Accurate predictions have been made of the recovery following long-term, low-stress creep in polypropylene by allowing for the physical aging (increase in retardation time) which occurs during the creep. Attempts to predict the recovery after creep at elevated stresses have been partially successful, and suggest further studies of an apparent deaging at the unloading stage and subsequent reactivation of aging. (Contract N00014-82-K-0612)

(AD-A288367; TR-99) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We have studied thin films composed of thin and thick wall template synthesized polypyrrole microtubules. We observe a crossover from three to one dimensional variable range hopping in our samples at low temperatures. Our results clearly indicate that the geometry of the microtubules has an influence on the conductivity. The transition temperature from 3 to 1 dimensional variable range hopping shifts to lower temperatures when high pressure is applied. The results are discussed on the basis of the geometry of the microtubules. DTIC

(Contract N00014-82-K-0612)
(AD-A288373; TR-98) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Nanochemistry is an emerging subdiscipline in the chemical and materials sciences that deals with the development of methods for synthesizing nanoscopic bits of a desired material and with chemical and other investigations of the nanomaterial obtained. My research group has been exploring a general method, called 'template-synthesis,' for preparing nanomaterials. This method entails synthesizing the desired material within the pores of a nanoporous membrane. The membranes employed have cylindrical pores of uniform diameter. In essence, we view each of these pores as a 'nanobeaker' in which a piece of the desired material is synthesized. We have used this method to prepare nanostructures composed of electronically conductive polymers, metals, semiconductors, and other materials. In this Accounts article, I discuss my work on template synthesis of electronically conductive polymer nanostructures. I will show that these conductive polymer nanostructures have interesting and unusual electronic properties and that these nanostructures provide an opportunity for exploring how molecular and supermolecular structure affect conductivity in conductive polymers. ADVANCED SOLID LUBRICANT FILMS BY ION-BEAM ASSISTED DEPOSITION
Irwin L. Singer, Robert N. Bolster, Larry E. Seitzman, Kathryn J. Wahl, Marshall B. Peterson (Wear Sciences, Inc., Arnold, MD.), and Robert L. Mowery 28 Nov. 1994 12 p Sponsored in part by ONR and SDIO Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288866; NRL/MR/6170-94-7633) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

NRL is developing advanced solid lubricating films for bearing assemblies. The films are deposited by ion-beam assisted deposition (IBAD) to thickness that can be controlled from 0.02 micrometers (1 micro inch) to greater than or equal to 1 micrometer (40 micro inches). Unlike evaporated or sputter-deposited films, IBAD films are dense and adhere well to virtually all solid surfaces. Durable films have been deposited on bearing steels, Ti alloys and many ceramic substrates, including Si3N4, alumina, SiC, TiN and CVD diamond. IBAD's multibeam capabilities have also been exploited to produce binary and ternary alloys over a wide range of stoichiometries. Studies of two solid lubricating films, MoS2 and ternary metal oxides, will be highlighted. IBAD MoS2 films exhibit reduced susceptibility to moisture degradation during storage. Alloyed MoS2 films show increased durability in sliding and rolling contact without sacrificing the ultra-low friction behavior of MoS2. For high temperatures, a class of binary metal oxide films are being investigated. Candidate lubricants have been chosen based on tribological behavior of oxide and predictions from thermodynamic phase diagrams. A recent study of the Cu-Mo-O system will be presented. DTIC

Ballistic impact experiments were performed on ceramic laminate targets at three scale sizes, nominally 1/3, 1/6, and 1/12, to quantify the effects of scale on various responses, in particular, the ballistics limit velocity. The experiments were carefully designed and controlled so that the different scale sizes were high fidelity replicas of each other. A variety of responses, such as residual projectile quantities, hole size, and the extent of bulging, were measured. Some of the measured quantities showed little or no dependence on scale size, whereas other quantities, particularly the ballistic limit velocity, were found to vary with scale size. The percentage difference was quantified, and the results extrapolated to estimate full scale response from the subscale tests. DTIC

THE EFFECT OF PROTEINS ON THE AGING PROPERTIES OF RADIATION VULCANIZED NATURAL RUBBER LATEX Master's Thesis
Lucille V. Abad 18 Mar. 1993 172 p Sponsored by the Philippine Nuclear Research Inst.Philippines; and the Takasaki Radiation Chemistry Research Establishment of the Japan Atomic Energy Research Inst. Japan
(DE95-603357; INIS-MF-14365) Avail: CASI HC A08/MF A02 (US Sales Only)

The effect of natural rubber latex (NRL) proteins on the aging properties of NRL films was investigated. SDS-PAGE electrophoresis of the rubber proteins in NRL (Sri-Lanka) indicated a total of 18 proteins. A sharp decrease in tensile strength was observed after aging when NRL films were leached in 1% NH4OH. However, when these films were soaked in ethanol prior to leaching, the aging properties approximated those of the unleached samples. Electrophoretic analysis of the proteins present in the NH3 extracts of leached RVNRL films showed a high concentration of the protein herein. This protein was not found in the NH3 extracts of ethanol soaked films. NRL proteins were shown to decelerate the aging process of Radiation Vulcanized Natural Rubber Latex (RVNRL) films. Among the proteins, herein exhibited good anti-aging properties. The hydrolyzates from NR proteins also enhanced considerably the aging properties of RVNRL. DOE

The goal of this research has been to find dispersants for ceramic processing applications. The polyelectrolytes currently in use in the industry are synthesized from toxic precursors which present health hazards to workers. We have investigated polyelectrolytes produced from natural sources such as bacteria and kelp, as well as some polymers which have been produced synthetically. The polyelectrolytes which we have investigated include polysaccharides (alginate and dextran) and polypeptides (polyglutamic acid and polyaspartic acid). Some have been obtained from cultures of bacteria grown in our laboratories, others have been obtained from chemical supply houses. In addition, we have investigated the feasibility of using an in situ process by which we incubate the polymer-producing bacteria in the presence of ceramic powders. In this system, polymer adsorbs to the powder in a high affinity state, allowing subsequent washing to remove the bacterial cells, while retaining the adsorbed polymer. DTIC

MATERIALS WITH SELF ORGANIZED SURFACES: 2D POLYMER ASSEMBLIES Technical Report, 1 May 1993 - 30 Apr. 1994
Samuel I. Stupp, Vassou LeBonheur, and Kenneth A. Walker 1 Dec. 1994 4 p Presented at the American Chemical Society Meeting, Anaheim, CA, 2-7 Apr. 1995 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-0534)
(AD-A288928; TR-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Our laboratory has developed the concept of 'bulk' synthesized 2D polymers through self assembly of reactive oligomers into layered structures. The products from these supermolecular reaction schemes are high molar mass flat macromolecules which in fusible systems retain their shape during solid to liquid phase transitions. We describe here a new system based on nanophase separated rodcoils functionalized at one terminus with the objective of producing 2D polymers with two chemically different surfaces. One surface of the macromolecule contains closely packed methyl groups and it is therefore highly hydrophobic, whereas the other is hydrophilic being composed of phenolic or carboxyl functions. Interestingly, solvent cast 'macroscopic' films of the layered assemblies develop spontaneously one hydrophobic surface and a very sticky one which is readily wet by water. This of a bulk material with self organized surfaces, an important objective for the exploitation of self assembly in manufacturing. Such materials would open the door to concepts such as self organized interfaces for composite materials, self organized tapes and membranes with chemically defined surfaces, as well as tubes with chemically defined lumina. RADIATION VULCANIZATION OF NATURAL RUBBER LATEX
Wan Manshol binWanZin and Norjanah bintiMohid 1994 25 p Presented at the National Seminar on the Assessment of IRPA Research Achievement in 5th Malaysian Plan: Industrial Sector, Kedah, Malaysia, 20-24 Dec. 1991 Limited Reproducibility: More than 20% of this document may be affected by poor print
(DE95-600026; INIS-MF-14332; CONF-9112185) Avail: Issuing Activity (Department of Energy (DOE)) (US Sales Only)

This paper describes the experimental techniques and the results of radiation vulcanization of natural rubber latex carried out on several high ammonia latices available in the country. The efficiency of various sensitizers and stabilizers used were evaluated in terms of the gamma radiation dose required to produce the maximum tensile strengths. The extent of crosslinking of RVNRL sample films were estimated by equilibrium swelling ratio measurements. The stability of pre-irradiated and post-irradiated samples were monitored using viscosity measurements as the parameter. DOE

RHEOLOGICAL MEASUREMENT METHODS FOR FIBRE FILLED PLASTICS
M. Rides Sep. 1994 34 p
(PB95-190088; NPL-DMM(A)-149) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

A review is presented of various rheological measurement methods that are suitable for characterizing the flow behavior of fiber filled plastics. The advantages and disadvantages of the various methods are discussed. Variation in the fiber content of a material has the greatest effect on its extensional flow behavior rather than on its shear flow behavior. Methods for characterizing extensional flow behavior of fiber filled plastics are also examined. Applications for rheological data include the simulation of injection and compression molding, resin transfer molding and for cure monitoring. NTIS

The SI unit of mass is the kilogram, defined as the mass of the 'international prototype', a cylinder of platinum-10% iridium alloy kept at the Bureau International des Poids et Mesures (BIPM) at Sevres, near Paris. This is the only remaining SI unit to be defined in terms of a physical artifact. Comparisons of mass can now be performed with great precision, but the accuracy with which the SI kilogram can be disseminated is limited by the stability of the artifacts themselves. Three main types of contamination are thought to occur at the surface; sorption of water vapor, carbonaceous contamination, and mercury. In this work we examine the contribution of the carbonaceous contamination, and how it can be reproducibly removed. We propose that the carbonaceous contamination consists of two distinct components, one from adsorbed hydrocarbons from the atmosphere, which form an adsorbed layer in dynamic equilibrium with the environment, and a more strongly bonded, cross-linked layer, similar to the dehydrogenated layers often observed on industrial platinum catalysts. This second form of carbonaceous contamination is more important because it grows monotonically and is typically in the range of tens of micrograms for a prototype in service; the latter part of the present work deals with the removal of carbonaceous contamination using UV radiation and ozone. One of the initial objectives of the project is to evaluate critically the test methods available for the determination of all the out-of-plane or through-thickness (T-T) tensile, compressive and shear properties. A decision analysis technique was applied to quantitatively evaluate each method in terms of 14 criteria, encompassing a number of key issues. These included data producibility, cost of fabrication, cost of testing, availability of a standard test method, ease of data reduction and accuracy of test data. The relative importance of the criteria was based on an assessment by industry. NTIS

DESIGN, FABRICATION, MODELING, AND OPTICAL CHARACTERIZATION OF ORGANIC POLYMER NONLINEAR DIRECTIONAL COUPLERS M.S. Thesis
John N. Berry Dec. 1994 136 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289327; AFIT/GEO/ENP/94D-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research was an investigation into the suitability of a recently developed polymer, polyphenylene, as a material for integrated optical circuits (IOC's). Polymers show great promise in the area of IOC's because of material processing advantages, compatibility with most existing integrated circuit technology, and relatively strong nonlinear optical characteristics. This thesis contains an overview of: dielectric waveguides, linear and nonlinear directional coupler theory; various models useful in the design and analysis of optical waveguides; the fabrication of three different waveguide designs; the experimental apparatus and procedure used to optically characterize the waveguides; and the experimental results of the characterization. Waveguiding of near infrared light through polyphenylene, in both a slab waveguide and strip-loaded guides, was observed for the first time in this polymer. Coupling of light between guides of a multi-channel directional coupler was also observed. No definitive conclusions concerning nonlinear effects are possible due to the non-identical, multi-channel nature of the fabricated waveguides. The results of this research indicate that polyphenylene is a candidate for use in IOC's and that the polymer should be the topic of further research. DTIC

CHARACTERIZATION OF OPTICAL POLYMERS FOR MULTI-LAYERED ELECTRO-OPTIC DEVICES Ph.D. Thesis
Lori E. Rohlev Oct. 1994 166 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1190)
(AD-A289255; ECE/GWOL/60) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Nonlinear optical (NLO) polymers could potentially replace standard inorganic electrooptic materials, such as LiNbO3 and GaAs, in integrated optoelectronic devices and systems. The large electrooptic coefficients and the low dielectric constants of poled polymers make them ideal for high-speed electrooptic applications. Electrooptic devices can be easily fabricated by spin coating the polymer onto a substrate, forming optical channels by bleaching and making material electrooptic by poling the channels. This simple fabrication procedure makes polymers ideal for multilayered applications. As new materials are developed and used in new configurations and applications, they must be characterized for optimum device design and performance. DTIC

Litton Poly-Scientific Security Products manufactures a 'shocking' sensor used to detect intrusion. The sensor functions as a make/break contact assembly with the movable contact being a gold plated brass disk (or 'slug'). Debris, drying stains, and other soils or contaminants able to interrupt the current flow through the contact assembly can create a false alarm. Therefore, a very high level of contact cleanliness is required. The drying process following electroplating was a six step process using CFC-113. A two step process using a perfluorocarbon was evaluated. Using ESCA, the new process was determined to be at least as good as the old six step process using CFC-113. Author

The Montreal Protocol and the 1990 Clean Air Act Amendments mandate CFC-113, other chlorinated fluorocarbons (CFC's) and 1,1,1-Trichloroethane (TCA) be banned from production after December 31, 1995. In response to increasing pressures, the Air Force has formulated policy that prohibits purchase of these solvents for Air Force use after April 1, 1994. In response to the Air Force policy, Martin Marietta Astronautics is in the process of eliminating all CFC's and TCA from use at the Engineering Propulsion Laboratory (EPL), located on Air Force property PJKS. Gross and precision cleaning operations are currently performed on spacecraft components at EPL. The final step of the operation is a rinse with a solvent, typically CFC-113. This solvent is then analyzed for nonvolatile residue (NVR), particle count and total filterable solids (TFS) to determine cleanliness of the parts. The CFC-113 used in this process must be replaced in response to the above policies. Martin Marietta Astronautics, under contract to the Air Force, is currently evaluating and testing alternatives for a cleanliness verification solvent. Completion of test is scheduled for May, 1994. Evaluation of the alternative solvents follows a three step approach. This first is initial testing of solvents picked from literature searches and analysis. The second step is detailed testing of the top candidates from the initial test phase. The final step is implementation and validation of the chosen alternative(s). Testing will include contaminant removal, nonvolatile residue, material compatibility and propellant compatibility. Typical materials and contaminants will be tested with a wide range of solvents. Final results of the three steps will be presented as well as the implementation plan for solvent replacement. Author

A SUMMARY OF ODS REPLACEMENT TECHNOLOGIES AT LITTON POLY-SCIENTIFIC
Charles William Reed *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 27-31 (For primary document see N95-27101 09-27)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Litton Poly-Scientific (LPS) has successfully determined CFC-113 and 1,1,1-trichloroethane replacement technologies for all its processes. More than 45,000 Kg/year (100,000 lbs/year) of each of these ozone depleting chemicals was being used in 1989. Replacement technologies include aqueous cleaning, organic solvents, solvent/surfactant systems, and perfluorocarbons. The ODS elimination has been realized with a significant net savings on yearly solvent expenditures. An active team involvement has been critical to the success of the endeavor. Technologies which were evaluated, but not used for various reasons, include the following: CO2 snow, supercritical CO2 extraction, perfluorocarbon drying, semi-aqueous cleaning (citrus based terpenes), volatile siloxanes, NMP, and hydrocarbon blends. Not all the replacement processes are optimized, however. In addition, new technologies are continuing to be evaluated as replacements for those presently being used. Most promising, at present, is solvent cleaning using ethyl lactate. Author

WIPE SOLVENT SUBSTITUTIONS FOR 1,1,1-TRICHLOROETHANE (TCA) AND METHYL ETHYL KETONE (MEK) AT HILL AIR FORCE BASE
S. Barney, J. Vidic, D. Frederick, S. Rasmussen, J. Jusko, and S. Edwards *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 53-59 (For primary document see N95-27101 09-27)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The purpose of this paper is to present the challenges faced by Hill Air Force Base in meeting the obligations in the Montreal Protocol and the Clean Air Act. Focus is on selecting substitute cleaners for the hand-wipe cleaning processes which use TCA and MEK. Candidate cleaners were subjected to laboratory testing to determine cleanability, corrosion potential, polysulfide sealant compatibility, evaporation rate, and effect on polyimide wiring. The top-ranking cleaners were categorized by their characteristic material properties. A low vapor pressure solvent blend (LVSB), an aliphatic hydrocarbon and an aqueous cleaner were selected to replace TCA and MEK in hand-wipe applications. Existing processes were modified and pilot testing was performed. The objectionable odor of the LVSB and the poor cleaning efficiency of the aqueous cleaner has limited implementation. The aliphatic hydrocarbon, on the other hand, has been well received and is currently being implemented. Methods of decreasing the solvent dry time and minimizing vapor emissions are in place. Surface analysis techniques will be used the future to determine the non-volatile residue and corrosion products left from the replacement cleaners. Author

In accordance with required eliminations of chlorofluorocarbon 113 (CFC-113) and 1,1,1- trichloroethane (TCA), Martin Marietta has evaluated non-ozone depleting chemicals for implementation at the Air Force PJKS facility. These replacements are intended for all operations in which CFC-113 and TCA were previously used, and are targeted at mechanical cleaning operations, electrical cleaning operations, and the replacement of an anti-seize lubricant. Selection criteria for mechanical cleaners include the cleaning power of the solvent, the compatibility with materials being cleaned, the cleaning ability after loading with dissolved contaminants, the toxicity and relative safety of using the cleaner, and the waste disposal requirements. In addition, because the PJKS facility conducts tests on propulsion systems for missiles and satellites, the cleaner must be compatible with liquid rocket propellants (Aerozine-50 fuel and nitrogen tetroxide oxidizer). Electrical processes involved the cleaning of rotary contacts used in amplifier modules. Replacement of an anti-seize compound used to lubricate bolt threads was also required. This material is used as a shop aid in protecting threaded fasteners from exposure to high stress, high temperature, or corrosive atmospheres. After conducting screening, demonstration, and validation tests, replacement candidates for these materials were selected. These candidates met or exceeded all technical requirements identified for their intended applications. Author

CO2 PELLET BLAST CLEANING AND DEGREASING: THE TRUE ENVIRONMENTALLY BENIGN TECHNOLOGY

Michael W. Lewis *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommitee Joint Workshop Jun. 1994 p 79-94 (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Frozen carbon dioxide (CO2) or dry-ice blast cleaning and degreasing technology utilizes a naturally occurring gas that's converted to a solid and is used as a projectile cleaning medium. The liquid CO2 used in this process is a recycled waste product from multiple industrial processes and therefore has no net effect on CO2 gas emissions. This process can be somewhat compared to grit blasting. However, dry-ice blasting leaves absolutely no residue and doesn't generate any waste whatsoever because it sublimates (reverts directly back to a gas) instantly upon impacting the object or surface being cleaned because dry-ice has no molecular density. This allows the process to clean machined surfaces without abrasion. The process also works well on non-metallic surfaces as long as well defined operating parameters are closely followed. What's left over is a surface cleanliness that cannot be attained by virtually any other single step cleaning process. Even Methylethylketone (MEK) surface preparation processes cannot duplicate this level of cleanliness according to Optically stimulated Electron Emission (OSEE) tests conducted in Europe. THE USE OF SUPERCRITICAL CARBON DIOXIDE FOR CONTAMINANT REMOVAL FROM SOLID WASTE **c45**

Carol L. J. Adkins, Edward M. Russick, H. Mike Smith (Allied-Signal Corp., Kansas City, MO.), and Ron B. Olson (Allied-Signal Corp., Kansas City, MO.) *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 95-103 (For primary document see N95-27101 09-27)

(Contracts DE-AC04-76DP-00613; DE-AC04-94AL-85000)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Supercritical carbon dioxide is being explored as a waste minimization technique for separating oils, greases and solvents from solid waste. The contaminants are dissolved into the supercritical fluid and precipitated out upon depressurization. The carbon dioxide solvent can then be recycled for continued use. Definitions of the temperature, pressure, flowrate and potential co-solvents are required to establish the optimum conditions for hazardous contaminant removal. Excellent extractive capability for common manufacturing oils, greases, and solvents has been observed in both supercritical and liquid carbon dioxide. Solubility measurements are being used to better understand the extraction process, and to determine if the minimum solubility required by federal regulations is met. Author

PRECISION PARTS CLEANING WITH SUPERCRITICAL CO2: PRACTICAL APPLICATIONS AND SOLUTIONS

Paula Gallagher-Wetmore, E. Moy, and V. Krukonis *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 105-114 (For primary document see N95-27101 09-27)

(Contract F04704-92-C-0017)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Supercritical fluids (SCF's) have long been known to display interesting dissolving capabilities. But the ramifications of utilizing SCF's as processing tools was not fully realized until 1955 when Todd and Elgin first suggested their use as extractive solvents. Over the past two decades supercritical fluids have been utilized as solvents for carrying out separations of materials in such diverse areas as foods, polymers, pharmaceuticals, petrochemicals and specialty chemicals, natural products, and explosives. More recently they have been used for non-extractive applications, such as recrystallization, deposition, reactions, and surface modification. The ability to tailor the solubility characteristics of supercritical fluids to suit a particular application forms the basis for processing with these unique solvents. Proper manipulation of operating temperature and pressure can result in selective extraction of a component from a mixture. As industrial and consumer awareness regarding the environmental and health hazards of traditional solvent use increases, it is anticipated that the utilization and acceptance of supercritical fluids as alternative solvents will become widespread. ETHYL LACTATE AS A SOLVENT ALTERNATIVE FOR CLEANING METAL PARTS

Elizabeth A. Hill and K. David Carter, Jr. *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 115-123 Sponsored by PURAC America, Inc. (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Cleaning tests and solvent analyses were performed with ethyl lactate to determine its effectiveness for cleaning metal parts. Nine contaminants were removed from stainless steel substrates using the solvent and ultrasonic agitation. The cleaning efficiencies were calculated from gravimetric measurements obtained with an electronic microbalance. All nine contaminants were removed with efficiencies better than 99.94%, using only ethyl lactate cleaning and rinsing. Further testing on two contaminants with Electron Scanning for Chemical Analysis (ESCA) showed that less than a monolayer of contaminant remained on the surfaces after the cleaning steps. The nonvolatile residue and metal ion content were also measured and determined to be acceptable for most precision metal cleaning applications. Preliminary compatibility tests were run on three metal alloys. Author

With the eventual phase-out of chlorofluorocarbons, and restrictive regulations concerning the use of cleaning solvents such as hydrochlorofluorocarbons, and other volatile organic compounds, it is essential to seek new, environmentally acceptable cleaning processes. In the DOE Complex and in industry, an environmentally sound process for precision cleaning of machined metal parts is one of the issues that needs to be addressed. At Sandia, we are investigating the use of supercritical carbon dioxide (CO2) as an alternative cleaning solvent for this application. Carbon dioxide is nontoxic, recyclable, and relatively inexpensive. Supercritical CO2 has been demonstrated as a solvent for many nonpolar organic compounds, including hydrocarbon-based machining and lubricating oils. The focus of this work is to investigate any corrosive effects of supercritical CO2 cleaning on metals. Sample coupons of several common metals were statically exposed to pure supercritical CO2, water saturated supercritical CO2, and 10% wt. methanol/CO2 cosolvent at 24,138 kPa (3500 psi) and 323 K (50 C) for 24 hours. Gravimetric analysis and magnified visual inspection of the coupons were performed before and after the exposure tests. Electron microprobe, x-ray photoelectron spectroscopy (XPS), and Auger electron surface analyses were done as needed where visual and gravimetric changes in the samples were evident. The results of these experiments will be reported. Author

Chlorofluorocarbon (CFC) solvents have been used effectively for parts cleaning within a number of diverse industries, including the electronics, aerospace, metal finishing, and medical industries. The phaseout of CFC production has resulted in the evaluation of supercritical carbon dioxide (CO2) as an environmentally acceptable, cost effective replacement solvent for a number of these parts cleaning applications. In addition to being non-toxic, non-flammable and non-hazardous, CO2 has a near ambient critical temperature of 31 C and a moderate critical pressure of 1070 psi. Solvent properties, such as density and viscosity, can be adjusted by relatively small changes in temperature and pressure, allowing CO2 to dissolve a wide range of organic compounds. This paper will report on the projected use of supercritical CO2 as a replacement solvent for military and industrial cleaning operations; the technical barriers to integration into the workplace; specific applications for CO2-based cleaning systems, and commercial manufacturing activity at CF TECH. EVALUATIONS OF THE EFFECTIVENESS OF ENVIRONMENTALLY BENIGN CLEANING METHODOLOGIES **c38**
James D. Rancourt *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 143-145 (For primary document see N95-27101 09-27)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Due to environmental concerns many very effective cleaning methodologies and materials must be replaced. Systems were developed in the past for which the performance had been verified. Now, old but environmentally benign cleaning methodologies, and new cleaning systems are being applied. It is necessary that the performance of these systems be documented. Analytical methods that can be used for materials inspection and quality assurance purposes will be presented. Author

THE BIODEGRADATION OF FUELS IN SOILS AND SEDIMENTS: DIFFERENCES AS A FUNCTION OF MINERALOGY **c45**
Sabine E. Apitz and Kathleen J. Meyers-Schulte (Computer Sciences Corp., San Diego, CA.) *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 155-163 Sponsored by Office of Naval Technology, SERDP, DERA, and the Aircraft Environmental Support Office (For primary document see N95-27101 09-27)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Experiments were carried out to determine the effects of substrate mineralogy on the biodegradability of fuel components. Samples of quartz sand (Fischer Sea Sand) and illite clay (API#35) were spiked with DFM (diesel fuel marine), aged, slurried and inoculated with DFM-acclimated soil microorganisms. Then, the concentrations of fuel components were monitored over time. While there was clear chromatographic and biomarker evidence of TPH (total petroleum hydrocarbon) biodegradation on the sands, illite samples showed no evidence of biogenic loss of aliphatic components. PAHs (polycyclic aromatic hydrocarbons) on the other hand, degraded equally well on both substrates, and in both cases, degraded to a much greater extent than did TPH. Author

BIOREMEDIATION OF CHLORINATED ORGANICS: PCBs, TCE, HCFCs **c23**
Ronald Unterman *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 165-167 (For primary document see N95-27101 09-27)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Halogenated organic compounds have been widely used industrially because of their combination of chemical properties and thermal stability. For example: the use of PCB's as a fire retardent fluid in heat exchangers, electrical equipment, and high temperature hydraulic fluids; TCE and other chlorinated solvents as nonflammable industrial solvents; and CFC's as nonreactive refrigerants and degreasing agents. However, the same chemical properties that confer upon these compounds their thermal and chemical stability, also confer upon them a general recalcitrance for biodegradation. Although these chemicals have been shown to be biochemically stable, research has shown that PCB's, TCE, and HCFC's are biodegradable, this work having been performed over the past twenty, ten, and two years, respectively. Different areas of bioremediation technologies and applications are addressed in this document. Derived from text

COMBINED USE OF GROUND WATER CIRCULATION (UVB) TECHNOLOGY AND IN SITU BIOREACTORS FOR ENHANCED BIOREMEDIATION OF SUBSURFACE CONTAMINATION **c45**
Jim G. Muller and E. J. Klingel (IEG Technologies, Inc., Gulf Breeze, FL.) *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 169-174 (For primary document see N95-27101 09-27)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Contamination of soil and ground water by trichloroethylene (TCE), a conventional degreasing agent, is recognized by the U.S. EPA as one of the more critical environmental problems facing the Nation today. Thus, from an end-user's perspective, conventional remedial technologies (such as pump-and-treat) are often unacceptable from a regulatory perspective, prohibitively expensive to implement, and technically inadequate. In an effort to overcome several factors known to limit the biodegradation of TCE (trichloroethylene) in the subsurface, we are focusing on the development of combined ground water circulation and contaminant vaporization technology coupled with an immobilized-cell bioreactor. The ground water circulation system is based on patented Vacuum-Vaporized Well (German: Unterdruck-Verdampfer-Brunnen; abbreviation UVB) technology (U.S. Patents 4,892,688; 4,943,305; 5,143,607; 5,095,975; 5,143,606; 5,171,103) for in situ treatment of the capillary fringe, phreatic and vadose zones contaminated with volatile organic compounds (VOCs), including NAPLs. The UVB system represents a promising technology for simultaneous in situ remediation of contaiminated soil and ground water, especially those contaminated with volatile and semi-volatile organics. Cleaning and maintenance of pipes, grease traps and organic waste tanks conventionally involves manual or chemical methods. These involve many limitations, in that they are labor intensive, expensive and pose waste disposal problems. Alternatively, microbial cleaners have the potential to clean more effectively while eliminating the use of acids, bases and solvents and reducing costs significantly. We are analyzing enzymatic and/or bacterial products available commercially, biosurfactants that are approved by the FDA and EPA, and microbes obtained from collection, holding and transfer (CHT) tanks, as well as bioemulsifier-producing microbes we have previously used for heavy hydrocarbon and lipase biodegradation. The objectives are to establish methods for evaluating the performance of microbial degreasing products, identify the best microbial products available, determine the best methods for the use of the products, and test them in shipboard CHT tanks. Microbial components have been screened for lipase activity and tested in functional assays for their ability to remove animal fat in benchtop models constructed of glass tubing. We have quantitated degreasing activity for correlation with lipase and esterase activity and established parameters for the use of some of the products. Author

Parallel plate oil/water separators (OWS) remove petroleum products (e.g. lubricating oils and hydraulic fluids) from shipboard oily bilge water. The oily waste is retained aboard and water meeting oily waste discharge limits is discharged. Separation of oil and water is dependent on laminar flow of oily bilge water through parallel corrugated polypropylene plates. During operation, oily sludge builds-up on the plates, disrupting the laminar flow and reducing the efficiency of the separator. To restore normal operating efficiency the separator must be dismantled and cleaned by hand. This is a labor intensive and costly task that may expose personnel to toxic and hazardous material. We have developed an in situ process that utilizes bacterial bioemulsifiers to remove oily sludge from the plates of the OWS and restore normal operating efficiency without need to dismantle the OWS. A laboratory system was developed for comparing the effectiveness of bacterial bioemulsifiers and biosurfactants in removal of oily sludge from polypropylene plates. We used this system to determine the optimum conditions required for emulsifier activity and selected bacterial bioemulsifiers and commercial products for testing in a model OWS system. The model 1 gallon/min OWS system was used to test selected bioemulsifiers and to optimize conditions for cleaning of the OWS system. Author

CLEANING OF PARTS FOR NEW MANUFACTURING AND PARTS REBUILDING c31

Jeff Doherty *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 215-223 (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Parts cleaning is the largest single expense, and the most time consuming activity, in rebuilding and new manufacturing. On average, 25% to 40% of the total labor and overhead burden is spent on cleaning. EPA and OSHA pressures add to the burden by making some methods and chemicals obsolete. Some of the processes and chemicals in current use will be curtailed and or outlawed in the future. How can a shops and industries make long term decisions or capital investments in cleaning and process improvements when the government keeps changing its rules? At the MART Corporation in Saint Louis, Missouri, we manufacture a line of cabinet-style batch cleaning machines known as Power Washers. Twenty years ago MART invented and patented the Power Washer process, a cleaning method that recycles wash solution and blasts contaminates as they are washed off the more heavily contaminated parts. Since the initial invention MART has continued to R&D the washing process and develop ancillary systems that comply with EPA and OSHA regulations. For applications involving new industrial parts or items requiring specification cleaned surfaces. MART provides filtration and solution conditioning systems, part drying operations, and triple rinsing. Units are available in stainless steel or higher alloys. We are not alone in the washer manufacturing business. You have many choices of cleaning solutions (no pun intended) which will perform in your operations and yield good results. As a manufacturer, we are interested in your success with our equipment. We have all heard the horror stories of companies having selected inappropriate cleaning systems and or processes which then brought the company to its knees, production wise. Assembly, appearance, warranty, and performance shortcomings of finished products can often be directly related to the cleaning process and its shortcomings. Author

Dillard *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 225-233 (For primary document see N95-27101 09-27)
(Contract NAS8-38100)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

MNASA, a quarter-scale space shuttle solid rocket motor, has historically been processed using environmentally and physiologically harmful chemicals. This program draws from previous testing done in support of full-scale manufacturing and examines the synergy and interdependency between environmentally acceptable materials for Solid Rocket Motor insulation applications, bonding, corrosion inhibiting, painting, priming and cleaning; and then implements new materials and processes in sub-scale motors. Tests have been conducted to eliminate or minimize hazardous chemicals used in the manufacture of MNASA components and identify alternate materials and/or processes following NASA Operational Environment Team (NOET) priorities. This presentation describes implementation of high pressure water refurbishment cleaning, aqueous precision cleaning using both Brulin 815 GD and Jettacin and insulation case bonding using ODC compliant primers and adhesives. A PRACTICAL APPROACH TO SOIL REMEDIATION **c45**

Paul F. Waters *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 235-239 (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

As a consequence of the rapid expansion of manufacturing and testing facilities, ignorance of the long-term harmful effects of exposure to many chemicals, and the improvident storage and disposal of harmful chemicals, scores of thousands of contaminated sites exist throughout the nation today. Several technologies have been advanced and applied in efforts to decontaminate the affected soils. Among the approaches are aeration, solvent extraction, incineration, steam distillation, electroosmosis, and the plasma arc. The technology discussed in this presentation is both feasible and economical because it is founded in the ancient art of reduction pyrolysis carried out in the reduction pyrolysis furnace (RPF). DESIGN CONSIDERATIONS IN SUPERCRITICAL FLUID TECHNOLOGY

Abstract Only

M. Lalith Kumar *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 241 (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Considerable interest has been exhibited in Supercritical Fluid Technology for extraction and cleaning. Supercritical fluid technology employs a mobile phase (or solvent) that is a highly compressed gas near or above its critical temperature and critical pressure points. Carbon dioxide is the most widely used supercritical fluid. Supercritical carbon dioxide is a superior solvent over conventional hydrocarbons, such as hexane or methylene chloride, for extraction because it is chemically inert, non-toxic, non-flammable non-corrosive and relatively inexpensive. The critical temperature of carbon dioxide is 31 C and the critical pressure is 73 atm. At the critical temperature of a substance, the vapor and liquid phases have identical densities. A gas cannot be liquefied when it is above its critical temperature, irrespective of the pressure. Above the critical temperature, the substance exists as a supercritical fluid. Supercritical fluid extraction (SFE) is becoming more widely accepted for the extraction of compounds due to the ability to achieve rapid, sensitive and reproducible extractions from many different types of matrices. The benefits are: (1) SF is rapid - a supercritical fluid has diffusion coefficients 1 - 2 orders of magnitude higher than comparable liquid solvents; (2) SF is selective - by varying pressure and temperature, SF can selectively extract compounds of interest from complex matrices or perform class fractionations; and (3) SFE eliminates hazardous solvents - carbon dioxide is an inexpensive non-toxic and nonflammable solvent. Thus, there is no-need to purchase and then dispose of liters and drums of organic solvents. Thar Designs has redesigned the various major products that are part of a supercritical fluid system. These redesigned products are not only superior in performance but also are relatively inexpensive to manufacture. Some of the features are use of ceramics for increased seal life, long term stability, temperature control and 'finger tight' closures. Author

RETROFITTING CONVENTIONAL VAPOR DEGREASERS TO USE A SOLVENT WASH/FLUOROCHEMICAL RINSE PROCESS

Kevin R. Hrebenar, Michael E. Hayes, Christine S. Fouts, and Robert D. Sell *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 243-249 (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Solvent wash/fluorochemical rinse processes offer a high-performance vapor degreasing method of cleaning which is economical, easy, fast, and efficient. They use no ozone-depleting solvents, toxic chemicals or water. Among the solvent wash/fluorochemical rinse processes, the Advanced Vapor Degreasing (AVD(TM*)) process avoids the use of flammables, as well. It works in virtually all vapor degreasing applications in the electronics, electrical, precision, and metalworking industries, providing highly effective degreasing of complex, delicate and difficult-to-clean parts. It is ideal for manufacturers who need to produce clean, dry parts without using water. The cleaning performance of the AVD process is as good as, or better than, conventional degreasing systems that use conventional vapor degreasing solvents. Laboratory and on-site tests in customers' factories have demonstrated that it is possible to effectively retrofit conventional vapor degreasers to be able to run the AVD process. Smaller systems like the Baron-Blakeslee Model MSR 120 or the Branson B-400 can be retrofitted, usually for costs between $15,000 and $20,000. AVD retrofitted equipment is conventional vapor degreasing equipment which has been modified to standards that enable it to use the AVD process satisfactorily, that is, it can produce clean, dry parts. The modifications to existing equipment include providing, as a minimum, the following: (1) 150% freeboard; (2) a rinse sump sparger; (3) filtration system in the boil sump; (4) ultrasonics in the boil sump; (5) chiller coil(s) above the primary condensing coils; and (6) ultrasonics in the rinse sump A detailed AVD process description will be provided. AVD process advantages and disadvantages relative to existing CFC solvent alternatives will be discussed. Cleaning results realized by several customers will also be provided. Author

FLUID DYNAMIC EFFECTS ON PRECISION CLEANING WITH SUPERCRITICAL FLUIDS **c34**

Max R. Phelps, M. O. Hogan, and L. J. Silva *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 259-268 See also N95-14663 (For primary document see N95-27101 09-27) (Contract DE-AC06-76RL-01830)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Pacific Northwest Laboratory staff have assembled a small supercritical fluids parts cleaning test stand to characterize how system dynamics affects the efficacy of precision cleaning with supercritical carbon dioxide. A soiled stainless steel coupon, loaded into a 'Berty' autoclave, was used to investigate how changes in system turbulence and solvent temperature influenced the removal of test dopants. A pulsed laser beam through a fiber optic was used to investigate real-time contaminant removal. Test data show that cleaning efficiency is a function of system agitation, solvent density, and temperature. These data also show that high levels of cleaning efficiency can generally be achieved with high levels of system agitation at relatively low solvent densities and temperatures. Agitation levels, temperatures, and densities needed for optimal cleaning are largely contaminant-dependent. Using proper system conditions, the levels of cleanliness achieved with supercritical carbon dioxide compare favorably with conventional precision cleaning methods. Additional research is currently being conducted to generalize the relationship between cleaning performance and parameters such as contaminant solubilities, mass transfer rates, and solvent agitation. These correlations can be used to optimize cleaning performance, system design, and time and energy consumption for particular parts-cleaning applications. Author

THE APPLICATION OF WATERJETS FOR CLEANING c34

D. A. Summers and Robert Fossey *In* Johns Hopkins Univ., Environmentally Benign Cleaning and Degreasing Technology: JANNAF Safety and Protection Subcommittee and Propellant Development and Characterization Subcommittee Joint Workshop Jun. 1994 p 269-277 (For primary document see N95-27101 09-27)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The last 25 years has seen a dramatic growth in the use of high pressure waterjets for cleaning purposes. Throughout recorded history and no doubt for a long time before that, the dual role of water as both a solvent and a lubricant has been one of the major ways of washing surfaces down regardless of what the surface was. Also, the power built into a waterjet stream has allowed it to be used in moving material. In ancient Egypt rivers were commonly diverted to erode valuable mineral deposits and it was not until 1852 that the modern innovation of hydraulic mining got its start in the hills around Sacramento. The power of the waterjets used in those mining operations were such that most of the gold in California and later in Idaho and many of the other western states was mined hydraulically. Subsequently, the technology has advanced considerably by the use of increasingly high pressures and smaller jets to the point where today abrasive laden waterjets at pressures above 35,000 psi are becoming the tool of choice for cutting glass, titanium, and composite materials. Applications of high pressure waterjets to cutting are usually however, governed by a different set of requirements to those of the cleaning operation. Specifically, while in a cutting or mining operation one is seeking to remove the most volume of material with the least amount of energy looking for deep cuts and applying a highly focused jet energy to the surface. Frequent cleaning requires the ability to remove only one or two surface coatings which may be very shallow. It is generally important that the underlying material or substrate is not damaged by the cleaning process, and thus, the energy of the jet must often be more diffuse. In contrast also with conventional cutting where the depth of the cut has great importance in cleaning it is the area which can be covered in a given time which better optimizes the process. An example of the types of requirement needed can be illustrated by the failure of paint. Where an overcoat of paint fails, that layer must be removed from the surface before a fresh protective coating can be applied. By the early 1980's the cost of this operation in the UK alone exceeded 600 million dollars. Derived from text

NEW RADIATION STABLE AND LONG-LIVED PLASTIC SCINTILLATORS

V. Senchishin, V. Koba, and O. Korneeva 1994 18 p

(DE95-608622; JINR-E-13-94-159) Avail: CASI HC A03/MF A01 (US Sales Only)

A study of the influence of the concentration of secondary addition, high concentrations of primary dopant, diffusion enhancer and stabilizer on radiation hardness is presented. It is concluded that the diffusion enhancing technique is the most powerful method for improving radiation hardness. A new polystyrene scintillator which contains 2% pT, 0.02% POPOP, 20% diffusion enhancer and 0.02% stabilizer gave 91% of initial light output immediately after 3 Mrad irradiation in air. Data are presented that show that scintillator prepared from commercial polymer is more radiation-hard and has greater light output than scintillator prepared from monomer. It is assumed that this difference is due to different molecular weight distributions. Some protocols for acceleration of aging (yellowing and crazing) are presented. It is shown that one of the main reasons for aging of plastic scintillators is residual monomer. DOE

LOW TEMPERATURE MATERIALS GROWTH AND PROCESSING DEVELOPMENT FOR FLAT PANEL DISPLAY TECHNOLOGY APPLICATIONS Quarterly Technical Report, 15 Aug. - 14 Nov. 1994

C. N. Berglund 14 Nov. 1994 11 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-93-1-0312)

(AD-A288970) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The goal of this phase of the project is to make DC, AC, transient measurements on the thin-film transistors (TFT's), fabricated by Professor Sigmon and his group at Arizona State University using low temperature processing techniques. From these measurements, SPICE parameters will be extracted and these results will be used for process monitoring and device and process optimization for display applications. This work was started by Rao Gudimetla on 10/1/94 and this technical report covers the period 10/1/94 to 12/1/94. The devices from ASU are expected to be ready in early 1995. Meanwhile, previously obtained measurements on TFT's fabricated at Tektronix Inc. are being used to establish a reliable extraction methodology. Both n- and p-channel TFT's, obtained from Tektronix Inc., were fabricated in silicon-implanted polysilicon, followed by a long time anneal without any grain boundary hydrogenation. The gate lengths are 12.5 and 5 microns with 100 micron width. S-parameter measurements (which were converted to Y-parameters) were made at several bias points over the frequency range of 300 kHz to 20 MHz. The following are the key accomplishments. (1) An often suggested AC equivalent circuit for TFT's was used to extract the parameters such as transconductance, gate to source capacitance, gate to drain capacitance, and drain to source capacitance as functions of frequency at different bias points. (2) A detailed analysis for the AC performance of TFT's, developed in the past by the author in the linear and triode regions of I-V data, is being compared with the extracted parameters of the devices and equivalent circuit. EVALUATION OF HIGH ESTER CONTENT PAO BASED SINGLE HYDRAULIC FLUID IN HIGH HUMIDITY CONDITIONS Final Report, 1 Jun. 1993 - 31 Jul. 1993

Ellen M. Purdy Nov. 1994 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289374; TARDEC-TR-13609) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A Polyalphaolefin/Ester based Fire Resistant Hydraulic Fluid was subjected to high humidity conditions to determine water absorbance tendencies of the fluid. Fluid was subjected to 300 hours of humidification in an environment of 85% Relative Humidity. Four distinct fluid formulations containing ester contents of 34%-40% by weight were found to absorb no more than 0.25% water after the 300 hour period. A performance evaluation of the humidified fluid revealed no loss in performance regardless of the absorbed water present in the fluid. Because satisfactory performance was obtained, the hydraulic fluid formulations can contain up to 40% ester with no loss of performance. The increased ester content in the fluid formulations will provide sufficient seal swell for Army hydraulic systems that use the PAO based hydraulic fluid. DTIC

N95-27325 Army Tank-Automotive Research and Development Command, Warren, MI.

USE OF CTFE AS AN ADDITIVE TO ENHANCE FIRE RESISTANCE OF SINGLE HYDRAULIC FLUID Final Report, 2 Feb. - 30 Sep. 1993

Ellen M. Purdy Nov. 1994 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289377; TARDEC-TR-13610) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A Polyalphaolefin/ester base fire resistant hydraulic fluid was reformulated to include chlorotrifluoroethylene (CTFE) as an additive to enhance fire resistance. CTFE was added to the formulation at 2%-10% by weight. Each of the formulations were evaluated for performance and flammability. Addition of the CTFE was found to promote excess foaming when tested for foaming characteristics. The formulations were adjusted to include an anti-foam additive to counteract this effect. The new formulations were found to provide satisfactory performance and improvement in fire resistance. Addition of CTFE increased the flash and fire points of the fluid. In addition, the autoignition temperature, hot manifold spray ignition temperature were both increased above what is available from MIL-HA6147O, the current military specification fire resistant hydraulic fluid. MAGNETIC RESONANCE IMAGING OF SOLVENT TRANSPORT IN POLYMER NETWORKS
R. E. Botto and G. D. Cody 1995 6 p
(Contract W-31-109-eng-38)
(DE95-007142; ANL/CHM/PP-80411) Avail: CASI HC A02/MF A01

The spectroscopic technique of magnetic resonance imaging (MRI) has recently provided a new window into transport of solvents in polymer networks. Diffusion of solvent as a rate-controlling phenomenon is paramount to understanding transport in many important industrial and biological processes, such as upgrading fossil fuels, film casting and coating, development of photoresists, design of drug-delivery systems, development of solvent resistant polymers, etc. By MRI mapping the migration of solvent molecules through various polymer specimens, researchers Robert Botto and George Cody of Argonne National Laboratory, with support from the Division of Chemical Sciences at DOE, were able to characterize and distinguish between different modes of transport behavior associated with fundamentally different types of polymer systems. The method was applied to rubbers, glassy polymers, and coals. In polymers shown to undergo a glass transition from a rigid to rubbery state, a sharply defined solvent front was observed that propagated through specimens in the manner of a constant velocity shock wave. This behavior was contrasted with a smooth solvent concentration gradient found in polymer systems where no glass transition was observed. The results of this analysis have formed the basis of a new model of anomalous transport in polymeric solids and are helping to ascertain fundamental information on the molecular architectures of these materials. THE RESPONSE OF HYDROTALCITE COATED ALUMINUM TO SEALING WITH TRANSITION METAL SALT SOLUTIONS
R. G. Buchheit and M. A. Martinez 1994 2 p Presented at the 187th Meeting of the Electrochemical Society, Reno, NV, 21-26 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-004767; SAND-94-3046C; CONF-950518-1) Avail: CASI HC A01/MF A01

Objective was to determine if the protective coating could be enhanced by filling intercrystalline spaces or by reinforcing the coating at intermetallic particles by exposure to aqueous transition metal salt solutions. Two oxy-anion analogs to chromate were used: permanganate and molybdate. Ce(3)(as Ce(NO3(sub 3)) was also studied. (Al alloys 2024-T3 and 6061-T6 were used as substrates.) Results are summarized. REVIEW OF ACTIVITIES IN USA ON HTS MATERIALS
D. E. Peterson 1995 5 p Presented at the 7th Conference on Superconductivity and Applications, Buffalo, NY, 7-9 Sep. 1994
(Contract W-7405-eng-36)
(DE95-006404; LA-UR-95-48; CONF-940926-6) Avail: CASI HC A01/MF A01

Rapid progress in attaining practical applications of High Temperature Superconductors (HTS) has been made since the discovery of these new materials. Many critical parameters influencing HTS powder synthesis and wire processing have been identified through a combination of fundamental exploration and applied research. The complexity of these novel materials with regard to phase behavior and physical properties has become evident as a result of these careful studies. Achieving optimal mechanical and superconducting properties in wires and tapes will require further understanding and synergy among several different technical disciplines. Highlights of efforts towards producing practical superconductors for electric power applications based on rare earth-, bismuth-, and thallium-based systems are reviewed. DOE

GROWTH OF HYDROGENATED AMORPHOUS SILICON (a-Si:H) ON PATTERNED SUBSTRATES FOR INCREASED MECHANICAL STABILITY
W. S. Hong, J. C. D. Nieto, O. Ruiz, and V. Perez-Mendez Dec. 1994 11 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC03-76SF-00098)
(DE95-006589; LBL-36398; CONF-941144-64) Avail: CASI HC A03/MF A01

Residual stress in hydrogenated amorphous silicon (a-Si:H) film, which causes substrate bending and delamination, is studied. The internal stress can be reduced by controlling deposition parameters, but it is known to produce a trade-off between stress and electronic quality. Selective area deposition, in which the deposition area is reduced by making islands, reduced the stress when the lateral dimension of the islands becomes comparable to the film thickness. The overall stress is reduced by approximately 40% when the lateral dimension is decreased to 40 (mu)m, but the adhesion was not improved much. However, substrates having a 2-dimensional array of inversed pyramids of 200 (mu)m in lateral dimension produced overall stress 3 to approximately 4 times lower than that on the normal substrates. Such substrates were prepared by anisotropic etching of silicon wafers. The inversed pyramid structure also has other advantages including minimized delamination and increased effective thickness. Computer simulation confirmed that the overall stress can be reduced by deposition on the pyramidal structure. DOE

THE DEVELOPMENT OF MECHANICAL STRENGTH IN A CERAMIC MATERIAL DURING FIRING
L. R. Bunnell and S. W. Piippo (Richland School District, WA.) Nov. 1994 8 p Presented at the National Educators' Workshop Update '94 Conference, Gaithersburg, MD, 7-9 Nov. 1994
(Contract DE-AC06-76RL-01830)
(DE95-004925; PNL-SA-25035; CONF-9411179-1) Avail: CASI HC A02/MF A01

This experiment was designed for high school students who have a very limited background in ceramic materials, but the experiments could also be used at the college level. The objective of the experiment is to teach students about the development of mechanical strength in a ceramic material as a result of the firing process and about testing methods used for brittle materials. In the experiment, clay-based ceramic bars of uniform circular cross section are prepared by extrusion. The bars are then fired at temperatures high enough to achieve high strength by development of a glassy bonding phase. Finally, the bars will be stressed to failure in a simple testing machine. This will quantify the increase in strength as a function of firing temperature. DOE

SMALL ANGLE NEUTRON SCATTERING STUDY OF THE MICELLE STRUCTURE OF AMPHIPHILIC BLOCK COPOLYMERS
H. Yamaoka (Kyoto Univ., Japan.), H. Matsuoka (Kyoto Univ., Japan.), K. Sumaru (Kyoto Univ., Japan.), S. Hanada (Kyoto Univ., Japan.), M. Imai (Tokyo Univ., Japan.), and G. D. Wignall 31 Jul. 1994 13 p Presented at the Neutron Scattering, Sendai, Japan, 11-14 Oct. 1994

(Contract DE-AC05-84OR-21400)
(DE95-006625; CONF-9410165-12) Avail: CASI HC A03/MF A01

The amphiphilic block copolymers of vinyl ether were prepared by living cationic polymerization. The partially deuterated copolymers for SANS experiments were especially synthesized by introducing deuterated phenyl units in the hydrophobic chain. SANS measurements were performed for aqueous solutions of these copolymers by changing H2O/D2O ratios. The SANS profiles indicate that the micelles in the present system exhibit a core-shell structure and that the size and shape of micelles are largely dependent on the length of hydrophobic chain. The micelle of shorter hydrophobic chain was found to be nearly spherical, whereas the micelle of longer hydrophobic chain was confirmed to have an ellipsoidal shape. DOE

STRUCTURAL CERAMICS INCORPORATING WHISKERS, PLATELETS, AND PARTICULATE PHASES
P. F. Becher, C. H. Hsueh, K. B. Alexander, H. T. Lin, W. H. Warwick, C. G. Westmoreland, and S. B. Waters 1995 22 p Presented at the 3rd Conference on Ceramic-Ceramic Composites, Mons, Belgium, 18-20 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007048; CONF-941059-2) Avail: CASI HC A03/MF A01

Advances in the development of ceramics toughened with whiskers, particles, or platelets are reviewed with emphasis on the development of both fracture strength and toughness. In the systems described here, the primary focus is on toughening attained by crack bridging processes (e.g., frictional bridging and pullout) in the wake of the crack tip. Examples of the influence of resultant improvements in other mechanical properties (e.g., strength, fatigue, and thermal shock resistance) are also given for whisker-reinforced aluminas. It is shown that similar increases in fracture toughness may also be brought about by the incorporation of platelet phases in ceramics, either by their addition or by their formation during densification. In addition, the development of ceramic matrix composites containing transformable tetragonal zirconia grains is discussed. Here, it is shown that both the zirconia grain size and content, combined with thermal expansion mismatch stresses, influence the transformability of the zirconia and the resultant transformation toughening effects. Examples reveal that by addressing the microstructural characteristics, as well as the reinforcement and matrix properties, high strength toughened ceramics with exceptional damage resistance can be developed. ECR PLASMA-ASSISTED DEPOSITION OF Al2O3 AND DISPERSION-STRENGTHENED AlO2
J. C. Barbour, D. M. Follstaedt, and S. M. Myers 1995 25 p Presented at the 9th International Conference on Ion Beam Modification of Materials, Canberra, Australia, 5-10 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-007743; SAND-94-2417C; CONF-950220-3) Avail: CASI HC A03/MF A01

Electron cyclotron resonance (ECR) O2 plasmas, in conjunction with electron-beam evaporation of Al, were used to grow thick AlO(x) films were varying but controlled composition and microstructure. The ion energy was varied from 30 to 190 eV, and growth temperatures varied from 35 C to 400 C. The ECR-film compositions were varied from AlO(0.1) to Al2O3 by controlling the plasma parameters and Al deposition rate. The Al-rich alloys exhibited a fine-grain (10-100 nm) fcc Al microstructure with (gamma)-Al2O3 precipitates approximately 1 nm, similar to that found in the gigapascal-strength O-implanted Al. The measured hardness of the ECR Al-O alloys approximately 3 GPa was also similar to the ion-implanted alloys which implies that the yield strength of the ECR material is approximately 1 GPa. Moreover, the Al-O alloys retain much of the elasticity of the Al metal matrix. As-deposited stoichiometric Al2O3 samples grown with an applied bias of -140 to -160 V at 400 C were fine-grain polycrystalline (gamma)-Al2O3. The amorphous films crystallized into the (gamma)-Al2O3 phase upon vacuum annealing to 800 C. DOE

A fact-finding team of American scientists and engineers visited Japan to assess the status of research and development and applications in biodegradable polymers. The visit was sponsored by the National Science Foundation and industry. In Japan, the team met with representatives of 31 universities, government ministries and institutes, companies, and associations. Japan's national program on biodegradable polymers and plastics evaluates new technologies, testing methods, and potential markets for biodegradables. The program is coordinated by the Biodegradable Plastics Society of Japan, which seeks to achieve world leadership in biodegradable polymer technology and identify commercial opportunities for exploiting this technology. The team saw no major new technology breakthroughs. Japanese scientists and engineers are focusing on natural polymers from renewable resources, synthetic polymers, and bacterially-produced polymers such as polyhydroxyalkanoates, poly(amino acids), and polysaccharides. The major polymers receiving attention are the Zeneca PHBV copolymers, Biopol(registered trademark), poly(lactic acid) from several sources, polycaprolactone, and the new synthetic polyester, Bionolle(registered trademark), from Showa High Polymer. In their present state of development, these polymers all have major deficiencies that inhibit their acceptance for large-scale applications. Author

US-Patent-Class-528-176; US-Patent-Class-528-183) Avail: US Patent and Trademark Office

Four phenylethynyl amine compounds - 3 and 4-aminophenoxy-4'-phenylethynylbenzophenone, and 3 and 4-amino-4'-phenylethynylbenzophenone - were readily prepared and were used to endcap imide oligomers. Phenylethynyl-terminated amide acid oligomers and phenylethynyl-terminated imide oligomers with various molecular weights and compositions were prepared and characterized. These oligomers were cured at 300 to 400 C to provide crosslinked polyimides with excellent solvent resistance, high strength and modulus, and good high temperature properties. Adhesive panels, composites, films, and moldings from these phenylethynyl terminated imide oligomers gave excellent mechanical performance.

AMORPHIZATION OF COMPLEX CERAMICS BY HEAVY-PARTICLE IRRADIATIONS

R. C. Ewing (New Mexico Univ., Albuquerque, NM.), L. M. Wang (New Mexico Univ., Albuquerque, NM.), and W. J. Weber Nov. 1994 13 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC06-76RL-01830)
(DE95-005725; PNL-SA-25579; CONF-941144-56) Avail: CASI HC A03/MF A01

Complex ceramics, for the purpose of this paper, include materials that are generally strongly bonded (mixed ionic and covalent), refractory, and frequently good insulators. They are distinguished from simple, compact ceramics (e.g., MgO and UO2) by structural features which include: (1) open network structures, best characterized by a consideration of the shape, size, and connectivity of coordination polyhedra; (2) complex compositions which characteristically lead to multiple cation sites and lower symmetry; (3) directional bonding; and (4) bond-type variations within the structure. The heavy particle irradiations include ion-beam irradiations and recoil-nucleus damage resulting from alpha-decay events from constituent actinides. The latter effects are responsible for the radiation-induced transformation to the metamict state in minerals. The responses of these materials to irradiation are complex, as energy may be dissipated ballistically by transfer of kinetic energy from an incident projectile or radiolytically by conversion of radiation-induced electronic excitations into atomic motion. This results in isolated Frenkel defect pairs, defect aggregates, isolated collision cascades, or bulk amorphization. Thus, the amorphization process is heterogeneous. Only recently have there been systematic studies of heavy particle irradiations of complex ceramics on a wide variety of structure-types and compositions as a function of dose and temperature. In this paper, we review the conditions for amorphization for the tetragonal orthosilicate, zircon (ZrSiO4); the hexagonal orthosilicate/phosphate apatite structure-type (X10(ZO4)6(F,Cl,O)2); the isometric pyrochlores (A(sub 1-2)B2O6(O,OH,F)(sub 0-1p)H2O) and its monoclinic derivative zirconotite (CaZrTi2O7); the olivine (derivative - hcp) structure types, alpha-(sup VI)A2(sup IV)BO4, and spinel (ccp), gamma-(sup VI)A2(sup IV)BO4. TUNGSTEN CARBIDE FRAGMENTATION: EXPERIMENTAL CHARACTERIZATION AND NUMERICAL MODELLING

E. S. Hertel, Jr. and D. E. Grady 1995 9 p Presented at the 15th International Symposium on Ballistics, Haifa, Israel, 21-24 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008521; SAND-94-2344C; CONF-950537-1) Avail: CASI HC A02/MF A01

Tungsten Carbide is a high density ceramic (generally found in ceramic/metal mixtures) with attractive shear and tensile strength properties in certain ballistic applications. We have determined a Hugoniot elastic limit of approximately 4 GPa, followed by strong hardening behavior, with spall strengths of 2.7-3.6 GPa. In addition, a series of experiments where Tungsten Carbide spheres impacted PMMA indicates that a sharp transition to fine-grained fragmentation occurred at impact velocities between 2.4 and 2.9 km/s. The well-characterized experiments described above were used to assess the effectiveness of CTH in predicting the axial and radial dispersion of the projectile after break-up. CTH has a fracture model that relies on a P(sub min) criteria to allow computational void to relieve a tensile condition. Comparisons with the experimental data were made using the P(sub min) model and an additional model based on an energy-based theory of Grady and Kipp. We found that the simple models are not capable of predicting the complex fragmentation behavior seen in the experiments. DOE

PREDICTION OF MATERIAL STRENGTH AND FRACTURE OF GLASS USING THE SPHINX SMOOTH PARTICLE HYDRODYNAMICS CODE

D. A. Mandell and C. A. Wingate Aug. 1994 31 p
(Contract W-7405-eng-36)
(DE95-004869; LA-12830) Avail: CASI HC A03/MF A01

The design of many military devices involves numerical predictions of the material strength and fracture of brittle materials. The materials of interest include ceramics, that are used in armor packages; glass that is used in truck and jeep windshields and in helicopters; and rock and concrete that are used in underground bunkers. As part of a program to develop advanced hydrocode design tools, the authors have implemented a brittle fracture model for glass into the SPHINX smooth particle hydrodynamics code. The authors have evaluated this model and the code by predicting data from one-dimensional flyer plate impacts into glass, and data from tungsten rods impacting glass. Since fractured glass properties, which are needed in the model, are not available, the authors did sensitivity studies of these properties, as well as sensitivity studies to determine the number of particles needed in the calculations. The numerical results are in good agreement with the data. DOE

ASSAY OF WEATHERING EFFECTS ON PROTECTIVE POLYMER COATINGS USING POSITRON ANNIHILATION SPECTROSCOPY

L. D. Hulett, Jr., S. Wallace, Jun Xu, B. Nielsen (Brookhaven National Lab., Upton, NY.), Cs. Szeles (Brookhaven National Lab., Upton, NY.), K. G. Lynn (Brookhaven National Lab., Upton, NY.), J. Pfau, and A. Schaub 1995 15 p Presented at the 6th International Workshop on Slow-positron Beam Techniques for Solids and Surfaces (SLOPOS6), Makuhari, Japan, 18-22 May 1994

(Contracts DE-AC05-84OR-21400; DE-AC02-76CH-00016)
(DE95-007040; CONF-9405198-4) Avail: CASI HC A03/MF A01

Polymer coatings, both with and without pigments, have been subjected to solar radiation and water spray weathering. The degrees of penetration of the weathering effects have been measured by injecting positrons of varying energy, i.e. to variable depths, into the films and observing the Doppler broadening of the annihilation radiation. The method is capable of detecting changes due to weathering effects at very early stages, long before visual examination reveals degradation. As little as one week of exposure caused measurable changes in the polymer structure, which were reflected in the Doppler broadening. Given further development, positron spectroscopy could possibly become a useful complement to the other methods of determining weatherabilities of protective polymer coatings. DOE

(DE95-007130; ANL/IPNS/CP-85110; CONF-941144-58) Avail: CASI HC A02

Lead-indium phosphate-lasses exhibit a number of useful properties such as a high index-of-refraction, low preparation temperature and melt viscosity, and good chemical durability. The structure of such a glass (composition in wt.%: 65 PbO, 29 P2O5, 6 In2O3) has been investigated by total neutron scattering using the GLAD diffractometer at Argonne's spallation neutron source IPNS. Peaks corresponding to the P-0, Pb-O/In-O, and O-O pairs were observed in the radial distribution function. The short-range structure in the -lass, in terms of average coordination numbers and bond distances, is compared with those of a pure P2O5 glass and with the crystal structure of lead pyrophosphate, Pb2P2O7. Unlike silicate glasses in which the SiO4 tetrahedra form a 3-dimensional network, the PO4 tetrahedra in phosphate glasses form a chain-like structure. The structural modification by the lead cations in phosphate glasses appears to occur mainly in the medium range-affecting, the lengths and connectivity of the chain-like structure. DOE

MANUFACTURING TAILORED PROPERTY CERAMIC COMPOSITES
Kevin G. Ewsuk and Larry W. Harrison 14 Nov. 1994 23 p Presented at the 96th Annual Meeting of the Ameri can Ceramic Society, Indianapolis, IN, 25-28 Apr. 1994 Prepared in cooperation with Du Pont de Nemours (E. I.) and Co., Wilmington, DE
(Contract DE-AC04-94AL-85000)
(DE95-006303; SAND-93-1875C; CONF-940416-32) Avail: CASI HC A03/MF A01

Composite materials are desirable for many advanced engineering applications where the properties of a single phase material cannot meet all of the service requirements; however, existing process technology has limited the development and commercialization of composites. Lack of reproducible sintering to high density is one of the major obstacles to commercializing ceramic composites. Final-stage, non-reactive liquid phase sintering (NLPS) theory provides metrics for sinterability that can be used as guidelines to design and manufacture dense ceramic-filled-glass (CFG) composites. Additionally, within the constraints defined by the NLPS theory, sum-property models can be used to predict CFG composite properties, and to design composites with properties tailored to specific applications. By integrating composite process models with composite property models, processable, application-tailored CFG composites for microelectronics packaging have been designed and fabricated. DOE

MODIFICATION OF THE OPTICAL PROPERTIES OF GLASS BY SEQUENTIAL ION IMPLANTATION
R. H. Magruder, III, D. H. Osborne, Jr. (Vanderbilt Univ., Nashville, TN.), and R. A. Zuhr 1994 13 p Presented at the 13th International Conference on the Application of Accelerators in Research and Industry, Denton, TX, 7-10 Nov. 1994 Sponsored by Martin Marietta Energy Systems, Inc.
(Contracts DE-AC05-84OR-21400; DAAH04-93-G-0123)
(DE95-007401; CONF-941129-15) Avail: CASI HC A03/MF A01

The linear and nonlinear optical properties of a series of samples formed by the sequential implantation of Ti, O and Au are examined. Energies of implantation for each ion were chosen using TRIM calculations to insure overlap of the ion distributions. The Ti was implanted with nominal doses of 1.2 and 2 x 10(exp 17) ions/sq cm. The samples were implanted with oxygen to the same nominal dose as the Ti. Au was then implanted with a nominal dose of 6 x 10(exp 16) ions/sq cm. The samples were subsequently annealed in oxygen at 900 C for two hours. The Ti and O are incorporated into the host network, while the Au forms nanosize colloids. The presence of the Ti in the substrate causes a shift in the surface plasmon resonance frequency of the Au metal colloids as well as an increase in the nonlinear response of the composites. The results are interpreted in terms of effective medium theory. DOE

COPPER CVD USING LIQUID COINJECTION OF (hfac)Cu(TMVS) AND TMVS
J. S. Custer, G. A. Petersen, P. M. Smith, J. E. Parmeter, C. A. Apblett, J. A. T. Norman, A. K. Hochberg, and D. A. Roberts 1994 5 p Presented at the Advanced Metallizaion for ULSI Applications in 1994, Austin, TX, 4-6 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE95-008155; SAND-94-2544C; CONF-9410178-1) Avail: CASI HC A01/MF A01

Copper chemical vapor deposition using liquid coinjection of the Cu(I) precursor (hfac)Cu(TMVS) along with TMVS has been demonstrated. The coinjection of TMVS with (hfac)Cu(TMVS) stabilizes the Cu precursor until it enters the reaction chamber, allowing for better control of the deposition and faster deposition rates. Using this technique, we have grown films with as-deposited resistivities of 1.86 +/- 0.04 (mu)(Omega)-cm, independent of film thickness. Deposition rates of well over 100 nm/min are possible. Good step coverage and gap fill down to 0.6 micrometer lines is demonstrated, with gap fill being limited by the large Cu grain sizes in these films. DOE

AMBIENT-PRESSURE SILICA AEROGEL FILMS
S. S. Prakash (New Mexico Univ., Albuquerque, NM.), C. J. Brinker (New Mexico Univ., Albuquerque, NM.), and A. J. Hurd 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-008161; SAND-95-0350C; CONF-941144-87) Avail: CASI HC A02/MF A01

Very highly porous (aerogel) silica films with refractive index in the range 1.006-1.05 (equivalent porosity 98.5-88%) were prepared by an ambient-pressure process. It was shown earlier using in situ ellipsometric imaging that the high porosity of these films was mainly attributable to the dilation or 'springback' of the film during the final stage of drying. This finding was irrefutably reconfirmed by visually observing a 'springback' of great er than 500% using environmental scanning electron microscopy (ESEM). Ellipsometry and ESEM also established the near cent per cent reversibility of aerogel film deformation during solvent intake and drying. Film thickness profile measurements (near the drying line) for the aerogel, xerogel and pure solvent cases are presented from imaging ellipsometry. The thickness of these films (crack-free) were controlled in the range 0.1-3.5 micrometers independent of refractive index. DOE

LOW TEMPERATURE DEPOSITION AND CHARACTERIZATION OF N- AND P-TYPE SILICON CARBIDE THIN FILMS AND ASSOCIATED OHMIC AND SCHOTTKY CONTACTS Semiannual Technical Report, 1 Jul. - 31 Dec. 1994
Robert F. Davis and Robert J. Nemanich Dec. 1994 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1500)
(AD-A289107) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Exposure of heated 6H-SiC wafers to SiH4 contained both in a gas stream and an activated plasma was investigated for low temperature SiC cleaning and oxygen removal prior to thin film deposition. UPS revealed the first observation of surface states on the cleaned 6H-SiC surface. Monocrystalline epitaxial films of Beta(3C)-SiC(111) and alpha(6H)-SiC(0001) were grown on vicinal (approximately 3.50 deg off (0001) towards) alpha(6H)-SiC(0001) substrates via gas-source MBE from 1050 to 1250 C using Si2H6 and C2H4. Undoped films were n-type; p-type films were achieved using Al evaporation during growth. The undoped 3C-SiC films grown on thin AlN buffer layers had carrier concentrations as low as 3 x 10(exp 15)/cu cm. Extremely efficient activation of n-type (Al) dopants has been achieved. Initial attempts at n-type doping using NH3 are also described. Surfaces of 6H-SiC(0001) homoepitaxial layers deposited on vicinal and on-axis 6H-SiC wafers by CVD have also been investigated using ultra-high vacuum scanning tunneling microscopy (UHV STM). The vicinal surface showed strongly undulating step configurations. The on-axis surface possessed much wider terraces and much smoother step undulations. Step heights on both surfaces were 2.5 A corresponding to a single bilayer containing one Si and one C layer. After annealing at T greater than 110 C for 3-5 min. in UHV. selected terraces contained honeycomb-like regions most likely caused by the transformation to graphite as a result of Si sublimation. CHROMATE-FREE CORROSION RESISTANT CONVERSION COATINGS FOR ALUMINUM ALLOYS
R. G. Buchheit, C. A. Drewien, M. A. Martinez, and G. E. Stoner (Virginia Univ., Charlottesville, VA.) 1995 10 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society, Las Vegas, NV, 12-16 Feb. 1995
(Contract DE-AC04-94DP-85000)
(DE95-007742; SAND-95-0280C; CONF-950201-2) Avail: CASI HC A02/MF A01

Inorganic polycrystalline hydrotalcite, Li2(Al2(OH)6)2 center-dot CO3 center-dot 3H2O, coatings can be formed on aluminum and aluminum alloys by exposure to alkaline lithium carbonate solutions. This process is conducted using methods similar to traditional chromate conversion coating procedures, but does not use or produce toxic chemicals. The coating provides anodic protection and delays the onset of pitting during anodic polarization. Cathodic reactions are also inhibited which may also contribute to corrosion protection. Recent studies have shown that corrosion resistance can be increased by sealing hydrotalcite coated surfaces to transition metal salt solutions including Ce(NO3)3, KMnO4, and Na2MoO4. Results from these studies are also reported. DOE

METHODS DEVELOPMENT FOR MEASURING AND CLASSIFYING FLAMMABILITY/COMBUSTIBILITY OF REFRIGERANTS. TASK 1: ANNOTATED BIBLIOGRAPHY Interim Summary Report
E. W. Heinonen and R. E. Tapscott Jun. 1994 118 p
(Contract DE-FG02-91CE-23810)
(DE95-007232; DOE/CE-23810/42G; NMERI-OC-94/31) Avail: CASI HC A06/MF A02

For Task 1 of the flammable refrigerant methods development contract, NMERI performed a literature search to identify references on the flammability of refrigerants. A database to store a bibliographic record of the literature search was then developed. This database is contained in the Microsoft Access(reg sign) relational database management system for Windows(trademark). Searches for applicable sources were made on-line using the STN(reg sign) scientific and technical network; off-line using the National Technical Information Service (NTIS) database; WorldCat CD-rom database; the University of New Mexico library search; the Air-Conditioning and Refrigeration Institute (ARI) Refrigerant Database; and personal contacts. Three specific areas were searched: refrigerant properties, flammability test methods, and ignition technology. Many of the articles retrieved fall into multiple categories. Ignition technology was included as a separate category because of the importance of the ignition process to flammability and the vast amount of information available on ignition of gaseous fuels, especially hydrocarbons. Over 90 separate references have been entered into the database. Two separate report formats have been developed to display the results of the literature search. Appendix B is the short report format--without abstract, while Appendix C is the long format-with abstract. DOE

(Contract DE-AC03-76SF-00098)
(DE95-008355; LBL-36405) Avail: CASI HC A03/MF A01

Temperature- and pH-sensitive hydrogels can be used to separate or concentrate proteins from dilute solution. Two possible separation processes are discussed here. Experimental partitioning data are used to compare the efficiencies of neutral, weakly acidic, weakly basic, and polyampholytic poly-N-isopropylacrylamide copolymer gels for separating cytochrome c from ovalbumin. For each process, attention is given to the influence of the solute partition coefficient and swelling equilibria on process efficiency. DOE

SYNTHESIS AND PROPERTIES OF LANTHANIDE-EXCHANGED PREYSSLER'S HETEROPOLYANIONS
Mark R. Antonio, J. Malinsky, and L. Soderholm 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-31-109-eng-38)
(DE95-007136; ANL/CHM/CP-83289; CONF-941144-78) Avail: CASI HC A02/MF A01

Na(+) in the Preyssler heteropolytungstate anion (NaP5W30O110)(sup 14-) can be exchanged for a trivalent lanthanide ion. The potential significance of this new class of lanthanide heteropolyanions relates to their applications in catalysis science. This view follows from the fact that Keggin heteropolyanions and their free acids are used as heterogeneous solid catalysts and homogeneous solution catalysts. The authors describe synthetic conditions that lead to the incorporation of Ce(3+) and Pr(3+) within the Preyssler anion, and the coprecipitation of Ce(3+) and the Preyssler anion. Initial studies indicate that the latter, coprecipitated, material deserves study for bifunctional catalytic activity. DOE

CESIUM/OXIDE INTERACTIONS FOR ULTRATHIN FILMS ON (ALPHA)-Al2O3(001) AND (ALPHA)-Al2O3(1(BAR 1)O2)
K. R. Zavadil and J. L. Ing (AEA Technology, Albuquerque, NM.) 1995 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-008159; SAND-95-0309C; CONF-941144-84) Avail: CASI HC A02/MF A01

The interaction of cesium at the (0001) and (1(bar 1)O2) surfaces of sapphire has been investigated using a variety of surface analytical techniques. Reflection mass spectrometric measurements yield initial Cs adsorption probabilities of 0.9 and 0.85 for the unreconstructed (0001) and (1(bar 1)O2) surfaces, respectively. The adsorption probability decreases dramatically for these surfaces at critical Cs coverages of 2.0 x 10(exp 14) and 3.4 x 10(exp 14) atoms/sq cm, respectively. Thermally induced reconstruction of the (0001) surface to form an oxygen deficient surface results in a decrease in the initial probability and capacity for Cs adsorption. Low energy electron diffraction (LEED) demonstrates that an intermediate, mixed domain surface yields an initial adsorption probability of 0.5 while a ((radical)31 x (radical)31) R (+/-) 9 deg reconstructed surface yields a value of 0.27. Thermal desorption mass spectrometry (TDMS) shows that surface reconstruction eliminates the high binding energy states of Cs (2.7 eV/atom), consistent with the observed changes in adsorption probability. In contrast, reconstruction of the (1(bar 1)O2) surface produces only minor changes in Cs adsorption. X-ray photoelectron spectroscopy (XPS) indicates that no formal reductive/oxidative chemistry takes place at the interface. We interpret the facile adsorption and strong binding of Cs on sapphire to result from Cs interacting with coordinatively unsaturated oxygen. DOE

WEIGHTLESS ENVIRONMENT TRAINING FACILITY (WETF) MATERIALS COATING EVALUATION, VOLUME 1 Final Report
1995 103 p
(Contract NAS9-18973)
(NASA-CR-188366-Vol-1; NAS 1.26:188366-Vol-1) Avail: CASI HC A06/MF A02

The Weightless Environment Training Facility Material Coating Evaluation project has included preparing, coating, testing, and evaluating 800 test panels of three differing substrates. Ten selected coating systems were evaluated in six separate exposure environments and subject to three tests for physical properties. Substrate materials were identified, the manner of surface preparation described, and exposure environments defined. Exposure environments included immersion exposure, cyclic exposure, and field exposure. Cyclic exposures, specifically QUV-Weatherometer and the KTA Envirotest were found to be the most agressive of the environments included in the study when all three evaluation criteria are considered. This was found to result primarily from chalking of the coatings under ultraviolet (UV) light exposure. Volumes 2 and 3 hold the 5 appendices to this report. Derived from text

DEVELOPMENT OF LOW-EXPANSION CERAMICS WITH STRENGTH RETENTION TO ELEVATED TEMPERATURES Final Report
D. A. Hirschfeld and J. J. Brown, Jr. (Virginia Polytechnic Inst., Blacksburg, VA.) Sep. 1994 140 p
(Contract DE-AC05-84OR-21400)
(DE95-005760; ORNL/Sub-86-22049/2) Avail: CASI HC A07/MF A02

The development of advanced engines has resulted in the need for new ceramic compositions which exhibit thermo-mechanical properties suitable for the engine environment, e.g., low thermal expansion, stability to 1,200 C, and thermal shock resistance. To meet these goals, a two phase research program was instituted. In the first phase, new oxide ceramics were identified in the AlPO4-(beta)-eucryptite, (beta)-cristobalite, mullite and zircon systems. This research focused on screening and property characterization of ceramics in the four systems. The most promising compositions in the AlPO4-(beta)-eucryptite and zircon systems were then further evaluated and developed in the second phase with the goal of being ready for prototype testing in actual engines. Of the compositions, calcium magnesium zirconium phosphate (zircon system) exhibits the most desirable properties and is presently being developed for commercialization. DOE

FUNCTIONALIZED BLOCK COPOLYMERS AS ADHESION PROMOTERS
M. S. Kent and R. Saunders 1995 4 p Presented at the 18th Annual Meeting of the Adhesion Society, Hilton Head, SC, 19-22 Feb. 1995
(Contracts DE-AC04-94AL-85000; W-31-109-eng-38)
(DE95-008158; SAND-95-0378C; CONF-950273-1) Avail: CASI HC A01/MF A01

The goal of this work is to develop novel functionalized block copolymers to promote adhesion at inorganic substrate/polymer interfaces. We envision several potential advantages of functionalized block copolymers over small molecule coupling agents. Greater control over the structure of the interphase region should result through careful design of the backbone of the copolymer. The number of chains per area, the degree of entanglement between the copolymer and the polymer matrix, the number of sites per chain able to attach to the substrate, and the hydrophobicity of the interphase region can all be strongly affected by the choice of block lengths and the monomer sequence. In addition, entanglement between the copolymer and the polymer matrix, if achieved, should contribute significantly to adhesive strength. Our program involves four key elements: the synthesis of suitable functionalized block copolymers, characterization of the conformation of the copolymers at the interface by neutron reflectivity and atomic force microscopy, characterization of the degree of bonding by spectroscopy, and measurement of the mechanical properties of the interface. In this paper we discuss block copolymers designed as adhesion promoters for the copper/epoxy interface. We have synthesized a diblock with one block containing imidazole groups to bond to copper and a second block containing secondary amines to react with the epoxy matrix. We have also prepared a triblock copolymer containing a hydrophobic middle block. Below we describe the synthesis of the block copolymers by living, ring-opening metathesis polymerization (ROMP) and the first characterization data obtained by neutron reflectivity. DOE

THE MINIMUM PORE SIZE OBTAINABLE IN A SILICA GEL DURING DRYING
S. Wallace, C. J. Brinker, and D. M. Smith (New Mexico Univ., Albuquerque, NM.) 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-008162; SAND-95-0391C; CONF-941144-86) Avail: CASI HC A02/MF A01

The pore size r(sub p) in a gel is determined by the extent of shrinkage of the gel network during drying. Shrinkage is driven by the collapse of the gel network in response to the capillary pressure P(sub c) exerted by the pore fluid. The extent of shrinkage depends on the balance between the capillary pressure P(sub c) in the pore fluid and the bulk modulus K(sub p) of the gel. The hydraulic pore radius, r(sub H) = 2V(sub p)/S(sub a), where V(sub p) is the pore volume and S(sub a) is the apparent N2 BET surface area, is often used to characterize the pore size of a gel. A series of acid catalyzed silica gels dried in pore fluids with different (gamma)(sub lv), showed that there is a limit to the minimum apparent r(sub H) obtainable in a gel, and when the volume fraction of porosity (phi) less than or equal to 0.37, r(sub H) becomes constant and approximately 0.8 nm. In contrast, experimental data show that the true pore size r(sub p) of gels continues to decrease when (phi) less than or equal to 0.37. Analysis of their adsorption isotherms show that while r(sub H) apparently stays constant: (1) the BET C constant continues to increase; (2) the width and average of their pore size distributions continue to decrease;

and (3) as shrinkage continues the gels eventually become non-porous to N2 at 77 K but are still porous to CO2 at 273 K. This paper reviews these results and addresses micropore formation in silica gels with the goal of determining how P(sub c) influences the final r(sub p), and why r(sub p) and r(sub H) diverge when (phi) less than or equal to 0.37. DOE

NEW DEVELOPMENTS FOR SOL-GEL FILM AND FIBER PROCESSING
A. J. Hurd 1995 8 p Presented at the International Conference on Novel Techniques in Synthesis and Processing, Rosemont, IL, 2 Oct. 1994
(Contract DE-AC04-94AL-85000)
(DE95-008175; SAND-95-0343C; CONF-9410319-1) Avail: CASI HC A02/MF A01

New insights into the development of microstructure in sol-gel films have recently been revealed by several diagnostic techniques, including imaging ellipsometry, 'chemical imaging' by fluorescent tracers, light scattering from capillary waves, and finite-element modeling. The evolution of porosity during the continuous transition from dilute sol to porous solid in restricted geometries such as films and fibers is becoming clearer through fundamental understanding of evaporation dynamics and capillarity. Hexylene-bridged polysilsesquioxanes can be prepared as mesoporous or non-porous xerogels simply by switching from basic to acidic polymerization conditions. In this study, we looked at the effect of monomer concentration on porosity of hexylene-bridged xerogels prepared under acidic and basic conditions. 1, 6-Hexylene-bridged polysilsesquioxanes were prepared by sol-gel polymerizations of 1, 6-bis(triethoxysilyl)hexane 1 with concentrations between 0.1 to 1.2 M in ethanol. Gelation times ranged from seconds for 1.2 M concentration to months for 0.2 M. The gels were processed into xerogels by an aqueous work-up and the dry gels characterized by scanning electron microscopy (SEM), solid state C-13 and Si-29 CP MAS NMR spectroscopy, and gas sorption porosimetry. DOE

COMPARISON OF BRIDGED POLYSILSESQUIOXANE XEROGELS PREPARED FROM METHOXY- AND ETHOXY-SILYL MONOMERS
Douglas A. Loy, Brigitta Baugher, Roger A. Assink, S. Prabakar (Advanced Materials Lab., Albuquerque, NM.), and Kenneth J. Shea (California Univ., Irvine, CA.) 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-005422; SAND-94-3196C; CONF-941144-29) Avail: CASI HC A02/MF A01

Hydrocarbon-bridged polysilsesquioxanes are prepared by the sol-gel polymerization of monomers with more than one trialkoxysilyl group attached directly to the bridging group by Si-C bonds. While the effects of varying the identity of the bridging group (length, rigidity, etc.), monomer concentration, and type of catalyst have been studied, the effect of different alkoxy ligands on the silicon atoms has not been investigated. For this study, 1, 6-bis(triethoxysilyl)hexane 1 and 1, 6-bis(trimethoxysilyl)hexane 2 were polymerized under acidic and basic conditions in ethanol and methanol, respectively, and in tetrahydrofuran (THF). The resulting gels were processed to afford xerogels that were characterized by SEM, solid state C-13 and Si-29 Cross Polarization Magic Angle Spinning (CP MAS) NMR spectroscopy, and nitrogen sorption porosimetry. SURFACE SCANNING TECHNIQUES TO LOCATE AND STUDY DEFECTS IN PAINTED ZINC AND ZINC ALLOY COATED STEELS
H. S. Isaacs (Korrosionsinstitutet, Stockholm, Sweden.), A. J. Aldykiewicz, Jr. (Korrosionsinstitutet, Stockholm, Sweden.), D. Thierry (Korrosionsinstitutet, Stockholm, Sweden.), and T. C. Simpson 1995 10 p Presented at the Corrosion 1995: National Association of Corrosion Engineers (NACE) International Annual Conference and Corrosion Show, Orlando, FL, 26-31 Mar. 1995
(Contract DE-AC02-76CH-00016)
(DE95-006099; BNL-61239; CONF-950304-13) Avail: CASI HC A02/MF A01

Current density and impedance mapping measurements have been used to locate and monitor corrosion and defects on painted surfaces in solution. Measurements are reported for painted zinc and aluminum-zinc alloy coated steel surfaces. When scratched, current density mapping showed corrosion of the metal coating started at localized sites in both dilute chloride and sulfate solutions. Different scribing techniques were tested exposing only the metal coating and both the coating and the underlying steel. Effect of roll forming was investigated. Current density mapping located corrosion susceptible defects on painted roll formed materials that were not readily discernible optically. Scanning ac mapping showed that artificially formed defects were readily observed. Local impedance variations with frequency were measured for simulated defects and defect free areas of painted surfaces. Variations in paint thickness and the presence of defects were detected using the ac techniques. DOE

[AN OVERVIEW OF ACTIVITIES AND ACCOMPLISHMENTS OF THE METALS AND CERAMICS DIVISION] Progress Report, 31 Dec. 1993
D. F. Craig, R. A. Bradley, and J. R. Weir, Jr. Jul. 1994 245 p
(Contract DE-AC05-84OR-21400)
(DE95-007020; ORNL-6780) Avail: CASI HC A11/MF A03

This report provides an overview of activities and accomplishments of the division from October 1992 through December 1993; the division is organized to provide technical support, mainly in the area of high-temperature materials, for technologies being developed by DOE. Activities span the range from basic research to industrial interactions (cooperative research and technology transfer). Sections 1-5 describe the different functional groups (engineering materials, high-temperature materials, materials science, ceramics, nuclear fuel materials). Sect. 6 provides an alternative view of the division in terms of the major programs, most of which cross group lines. Sect. 7 summarizes external interactions including cooperative R and D programs and technology transfer functions. Finally, Sect. 8 briefly describes the division's involvement in educational activities. Several organizational changes were effected during this period. DOE

MOLECULAR MODELING: AN APPROACH FOR THE STUDY OF PIEZOELECTRIC POLYMERS Final Report
George J. Kavarnos 12 Dec. 1994 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289821; NUWC-NPT-TR-10771) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes the use of molecular modeling and computational chemistry techniques to investigate and tailor the piezoelectric properties of polyvinylidene fluoride (PVDF) and its copolymer with trifluoroethylene (PVDF-TrFE) for underwater hydrophone and acoustic projector applications. The effect of changing the ratios of vinylidene fluoride and trifluoroethylene monomers was studied using a combination of semiempirical molecular orbital theory, molecular mechanics, and crystal packing approaches. Molecular mechanics calculations on model end-capped polymer chains show that the tgtg'conformation of PVDF is 0.5 to 0.7 kcal/mol more stable than the all-trans formation but that for copolymer compositions less than 90 mol% vinylidene fluoride (VDF), the all-trans conformation is favored. Crystal packing calculations confirm the stability of the tgtg' for PVDF and the all-trans for the copolymers. To calculate the elastic compliances of PVDF and copolymer unit cell crystals along the poling direction, the b-axes were deformed in small increments and the crystal packing energies of each deformed structure were calculated. This procedure was used to determine the elastic compliances, which were calculated to be 2.59 x 10(exp -11)sq m/N for PVDF, 3.97 x 10(exp -11)sq m/N for 75 mol% VDF copolymer, and 5.38 x 10(exp -11)sq m/N for 50 mol% VDF copolymer. The d33c constants of the unit cells were calculated to be -3.3 pC/N for PVDF, -4.0 pC/N for 75 mol% VDF copolymer, and -4.3 pC/N for 50 mol% VDF copolymer. Although these values are much lower than the experimental d33 constants of semicrystalline polymer, a procedure used to calculate the d33 constants of semicrystalline polymer yields d33 constants much more in agreement with the experimental values. DEFORMATION BEHAVIOR OF THIN LUBRICANT FILMS AT ELEVATED PRESSURE
Scott Bair, F. Qureshi, Y. K. Lee, and W. O. Winer Dec. 1994 99 p Sponsored by ONR Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288906) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The elastohydrodynamic (EHD) regime of lubrication is responsible for the generation of a protective film and the transfer of shear across concentrated contacts in many machine elements including bearings, cams and gears. It is now understood that small scale EHD plays a major role in the boundary lubrication of rough surfaces. Many high pressure metal working operations share the pressure and kinematics of elastohydrodynamics. A complete solution of the EHD problem, however, requires a thorough knowledge of the lubricant constitutive behavior and the attending properties as functions of temperature and pressure. The Newtonian assumption alone is inadequate. DTIC

SUPERCOOLED LIQUID DYNAMICS FOR THE CHARGED HARD-SPHERE MODEL
S. K. Lai and S. Y. Chang (National Central Univ., Chung-Li, Taiwan.) Aug. 1994 15 p
(DE95-609158; IC-94/267) Avail: CASI HC A03/MF A01 (US Sales Only)

We study the dynamics of supercooled liquid and the liquid-glass transition by applying the mode coupling theory to the charged hard-sphere model. By exploiting the two independent parameters inherent in the charged hard-sphere system we examine structurally the subtle and competitive role played by the short-range hard-core correlation and the long-range Coulomb tail. It is found in this work that the long-range Coulombic charge factor effect is generally a less effective contribution to structure when the plasma parameter is less than 500 and becomes dominant when it is greater thereof. To extend our understanding of the supercooled liquid and the liquid-glass transition, an attempt is made to calculate and to give physical relevance to the mode-coupling parameters which are frequently used as mere fitting parameters in analysis of experiments on supercooled liquid systems. This latter information enables us to discuss the possible application of the model to a realistic system. DOE

(AD-A288870; DU/DC/TR-46) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The lithium arsenides (Li2(mu2-As(SiMe3)2)(mu3-As(SiMe3)2)(THF))2 (I) THF = tetrahydrofuran) and (Me3Si)2AsLi(THF)22 (II) were isolated and their solid-state structuresdetermined by X-ray methods. Compound I crystallizes in the monoclinic system, space group P2(sub 1)/c, with a = 10.147(1) A, b = 19.665(2) A, c = 16.768(2) A, p = 107.78(1) and Z = 2. The core structure consists of an LiAs4 ladder-like framework with four antiparallel adjacent As-Li rungs. The two lithium atoms of the central ring each bridge three arsenic centers while the two lithium atoms belonging solely to the outer rings each span two arsenic atoms and are coordinated to one THF molecule. Monoclinic crystals of compound II belong to space group C2/c, with a = 17.877(4) A, b = 14.077(3) A, c = 19.006(4) A, p = 109.16(2) and Z = 4. The structure consists of a centrosymmetric dimer containing a four-membered As-Li-As-Li ring wherein each lithium atom is coordinated to two molecules of THF. DTIC

The previous 'Art of Injector Design' is maturing and merging with the more systematic 'Science of Combustion Device Analysis.' This technology can be based upon observation, correlation, experimentation and ultimately analytical modeling based upon basic engineering principles. This methodology is more systematic and far superior to the historical injector design process of 'Trial and Error' or blindly 'Copying Past Successes.' The benefit of such an approach is to be able to rank candidate design concepts for relative probability of success or technical risk in all the important combustion device design requirements and combustion process development risk categories before committing to an engine development program. Even if a single analytical design concept cannot be developed to predict satisfying all requirements simultaneously, a series of risk mitigation key enabling technologies can be identified for early resolution. Lower cost subscale or laboratory experimentation to demonstrate proof of principle, critical instrumentation requirements, and design discriminating test plans can be developed based on the physical insight provided by these analyses. A NUMERICAL MODEL TO PREDICT THE FATE OF JETTISONED AVIATION FUEL M.S. Thesis
Karl Durant Pfeiffer Dec. 1994 107 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289336; AFIT/GCS/ENC/94D-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

While airborne, military and civilian aircraft must occasionally jettison unburned aviation fuel into the atmosphere. This research investigates the fate of a jettisoned fuel (e.g. JP-4, JP-8, etc.) from initial release to final ground fall by numerically modeling the physical phenomena governing the fate of this fuel: evaporation, advection, and dispersion. Using previous work in evaporation and free fall of fuel droplets as a foundation, this thesis presents an integrated evaporation advection and dispersion model designed to run under the resources of a typical personal computer. This integrated model is capable of using near real-time meteorological data (i.e. vertical profiles of temperature, pressure and wind) in all model calculations. Physical assumptions in the numerical model are presented, along with sample model calculations supporting these assumptions. Model calculations performed for two jettison scenarios show good agreement with previously published results. DTIC

HYDROGEN PROGRAM
Feb. 1995 28 p
(DE94-011827; DOE/GO-10095-088) Avail: CASI HC A03/MF A01

Hydrogen is an energy carrier with the potential to join electricity as a key component of a sustainable energy system. As an energy carrier and fuel, its future integration into the energy economy will help make renewable energy sources viable and practical. Primary sources are used directly to provide energy for services, but often they are used to create an energy carrier, such as electricity, to move the energy from the place of production to where it is needed to provide goods and services for society. Hydrogen has the potential to be a more versatile energy carrier than electricity. In the future, it may be produced cost effectively from renewable energy sources, then stored and transported for use in home and office heating, generating electricity, industrial processes, and surface and air transportation. It can accomplish this while also preventing pollution by substituting for and reducing the use of fossil fuels. The benefits of hydrogen make it the ideal component of a renewable, sustainable energy system of the future. It can be produced from water -- an abundant supply sources -- using direct sunlight, renewable electricity, and some biological organisms. When burned directly as a fuel, or converted to electricity, its principal by-product is water, which can be safely returned to the environment or reused to produce more hydrogen. The versatility of hydrogen will enable the more rapid expansion of the use of domestic renewable energy sources than might occur with electricity alone, resulting in reduced energy imports. Hydrogen energy has the potential for substantially contributing to the reduction of climate-changing emissions and other atmospheric pollutants. Unfortunately, the widespread use of hydrogen energy is not currently feasible because of economic and technological barriers. Hydrogen is presently used in a variety of industrial applications and, from this base, research and development will move hydrogen into widespread energy applications. DOE

ALTERNATIVE FUELS AND VEHICLES CHOICE MODEL
D. L. Greene Oct. 1994 80 p
(Contract DE-AC05-84OR-21400)
(DE95-005695; ORNL/TM-12738) Avail: CASI HC A05/MF A01

This report describes the theory and implementation of a model of alternative fuel and vehicle choice (AFVC), designed for use with the US Department of Energy's Alternative Fuels Trade Model (AFTM). The AFTM is a static equilibrium model of the world supply and demand for liquid fuels, encompassing resource production, conversion processes, transportation, and consumption. The AFTM also includes fuel-switching behavior by incorporating multinomial logit-type equations for choice of alternative fuel vehicles and alternative fuels. This allows the model to solve for market shares of vehicles and fuels, as well as for fuel prices and quantities. The AFVC model includes fuel-flexible, bi-fuel, and dedicated fuel vehicles. For multi-fuel vehicles, the choice of fuel is subsumed within the vehicle choice framework, resulting in a nested multinomial logit design. The nesting is shown to be required by the different price elasticities of fuel and vehicle choice. A unique feature of the AFVC is that its parameters are derived directly from the characteristics of alternative fuels and vehicle technologies, together with a few key assumptions about consumer behavior. This not only establishes a direct link between assumptions and model predictions, but facilitates sensitivity testing, as well. The implementation of the AFVC model as a spreadsheet is also described. DOE

TANK PRESSURE CONTROL IN LOW GRAVITY BY JET MIXING Final Report
Michael D. Bentz Mar. 1993 201 p A videocassette supplement Lewis Video 93-219 is available through NASA. Lewis Research Center Video Dept.
(Contract NAS3-25363; RTOP 589-01-2C)
(NASA-CR-191012; NAS 1.26:191012) Avail: CASI HC A10/MF A03

The Tank Pressure Control Experiment (TPCE) is a space experiment developed to help meet the need for a critical aspect of cryogenic fluid management technology: control of storage tank pressures in the absence of gravity by forced convective mixing. The experiment used a 13.7-liter tank filled to a constant 83 percent level with refrigerant 113 at near saturation conditions to simulate the fluid dynamics and thermodynamics of cryogenic fluids in space applications. The objectives of TPCE were to characterize the fluid dynamics of axial jet-induced mixing in low gravity, to evaluate the validity of empirical mixing models, and to provide data for use in developing and validating computational fluid dynamic models of mixing processes. TPCE accomplished all of its objectives in flight on Space Shuttle Mission STS-3 in August of 1991. The range of flow patterns photographed generally confirmed a prior correlation based on drop tower tests. A closed-form equation derived from a simple thermodynamic model was found to provide a first-order prediction of the pressure reduction time as a function of mixer parameters, tank size, and fluid thermophysical properties. Low energy mixing jets were found to be effective and reliable at reducing thermal non-uniformities, promoting heat and mass transfer between the phases, and reducing tank pressure. Author

THE EFFECT OF AVIATION FUELS CONTAINING LOW AMOUNTS OF STATIC DISSIPATER ADDITIVE ON ELECTROSTATIC CHARGE GENERATION
May 1994 132 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A280075) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of the CRC program was to determine whether commingled fuels containing low levels of static dissipater additive pose any additional electrostatic hazard over unadditized fuel. Specifically, the program conducted the necessary experiments to determine electrostatic effects of commingled fuels containing static dissipater additive with a conductivity less than 50 pico-Siemens/meter (pS/m). It was also a goal of this program to survey existing systems and make an assessment whether future fueling systems could cause additional electrostatic hazards during the fueling operation. In order to achieve these goals, it was the scope of this program: to assess the range of conductivities present in Jet A at various locations; to assess the charging tendency of Jet A presently being used in the United States; to perform laboratory scale tests to further study the charging tendency of ASA-3 and Stadis 450 in both commingled Jet A and clay treated Jet A as needed to verify the results of the other tests; and to develop a database of the residence times typical of existing fueling systems. SURFACTANTS AND DESENSITIZING WAX SUBSTITUTES FOR TNT-BASED SYSTEMS Final Report, 2 Jul. 1992 - 1 Jul. 1994
Gary Statton and Robert C. Taylor Oct. 1994 263 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F08630-92-C-0058)
(AD-A289652; WL-TR-94-7058) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

MACH I, Inc. developed three polyvinylpyrrolidones (Ganex resins) that are effective emulsifiers for microcrystalline or selected substitute desensitizing waxes in AFX-644 TNT melt cast bomb explosive. Ganex resins also are excellent dispersants for TNT melt casting and PBX in which they provide important benefits: wetting, coating, dispersion, lubrication, thinning, void filling, desensitization, and increased production rate. Ganex resins are expected to be effective emulsifiers and dispersants with microcrystalline desensitizing waxes or the recommended substitutes in any melt cast system such as Compositions B, HBX-1, D-2, and H-6. Furthermore, by reducing viscosity Ganex resins are expected to facilitate processing of PBX compositions such as AFX-931 in batch mixers as well as continuous mixers (e.g., twin-screw extruders). The Ganex surfactants appear promising for use in most munitions mixing processes for production of: ammunition, bombs, missiles, projectiles, demolition charges and special purpose devices. MACH I, Inc. also developed promising polar wax substitutes, having different desensitizing mechanisms, to enhance the benefits cited above. These substitutes offer greater formulation flexibility than conventional waxes to mitigate possible fuzing insensitivity or loss of explosive power. In contrast to conventional desensitizing wax, they are easier to emulsify and are dependably available in ample quantity and consistent quality. DTIC

DESIGN AND DEVELOPMENT OF EXPERIMENTAL FACILITIES FOR SHORT DURATION, LOW-GRAVITY COMBUSTION AND FIRE EXPERIMENTS Final Report, 25 May 1993 - 5 May 1994
Jun. 1994 198 p
(Contract NCC3-312; RTOP 656-61-23)
(NASA-CR-195458; E-9579; NAS 1.26:195458) Avail: CASI HC A09/MF A03

This report contains the results of three projects conducted by undergraduate students from Worcester Polytechnical Institute at the NASA's Lewis Research Center under a NASA Award NCC3-312. The students involved in these projects spent part of the summer of 1993 at the Lewis Research Center (LeRC). The Principal Investigator at Worcester Polytechnic Institute was Professor Vahid Motevalli. Professor Motevalli served as the principal project advisor for two of the three projects which were in Mechanical Engineering. The third project was advised by Professor Duckworth of Electrical and Computer Engineering, while Professor Motevalli acted as the co-advisor. These projects provided an excellent opportunity for the students to participate in the cutting edge research and engineering design, interact with NASA engineers and gain valuable exposure to a real working environment. This report has been divided to three sections, representing the outcome of each of the separate projects. The three reports which have been written by the students under the supervision of their advisors have been compiled into a combined report by Dr. Motevalli. Each project report is presented here as a section which is essentially self-contained. Each section contains chapters introducing the problem, solution approach, description of the experiments, results and analysis, conclusions and appendixes as appropriate. Author (revised)

DEVICE AND METHOD FOR SCREENING CRYSTALLIZATION CONDITIONS IN SOLUTION CRYSTAL GROWTH Patent Application
Daniel C. Carter, inventor (to NASA) 17 Apr. 1995 43 p
(NASA-Case-MFS-28985-1; NAS 1.71:MFS-28985-1;
US-Patent-Appl-SN-422963) Avail: CASI HC A03/MF A01

A device and method for detecting optimum protein crystallization conditions and for growing protein crystals in either 1g or microgravity environments comprising a housing, defining at least one pair of chambers for containing crystallization solutions is presented. The housing further defines an orifice therein for providing fluid communication between the chambers. The orifice is adapted to receive a tube which contains a gelling substance for limiting the rate of diffusive mixing of the crystallization solutions. The solutions are diffusively mixed over a period of time defined by the quantity of gelling substance sufficient to achieve equilibration and to substantially reduce density driven convection disturbances therein. The device further includes endcaps to seal the first and second chambers. One of the endcaps includes a dialysis chamber which contains protein solution in which protein crystals are grown. Once the endcaps are in place, the protein solution is exposed to the crystallization solutions wherein the solubility of the protein solution is reduced at a rate responsive to the rate of diffusive mixing of the crystallization solutions. This allows for a controlled approach to supersaturation and allows for screening of crystal growth conditions at preselected intervals. NASA

APPARATUS FOR DIFFUSION CONTROLLED DIALYSIS UNDER MICROGRAVITY CONDITIONS Patent Application
Daniel C. Carter, inventor (to NASA) 27 Feb. 1995 14 p
(NASA-Case-MFS-28986-1; NAS 1.71:MFS-28986-1;
US-Patent-Appl-SN-394862) Avail: CASI HC A03/MF A01

Apparatus for implementing crystal growth by allowing mixing of solutions under microgravity conditions includes a housing within which a number of pairs of chambers are formed. The chambers of each pair are aligned and a rotary valve is positioned between the chambers of each pair. When the valve is in a first position one chamber of each pair may communicate with the other chamber. A separate valve is provided for each pair of chambers so that each pair of chambers may be activated independently of the others and sequentially at selected intervals. Protein solution may be located within a small cavity in a cap which closes one of the chambers of a pair, and the cavity in the cap is closed by a dialysis membrane. The length of certain pairs of chambers may differ from the length of other pairs of chambers to optimize conditions for various dialysis productions, and wicking material may be incorporated into selected chambers for controlling the critical approach to supersaturation. MICROGRAVITY SCIENCE AND APPLICATIONS. PROGRAM TASKS AND BIBLIOGRAPHY FOR FY 1994
Mar. 1995 761 p
(NASA-TM-4677; NAS 1.15:4677) Avail: CASI HC A99/MF A06

This annual report includes research projects funded by the Office of Life and Microgravity Sciences and Applications, Microgravity Science and Applications Division, during FY 1994. It is a compilation of program tasks (objective, description, significance, progress, students funded under research, and bibliographic citations) for flight research and ground-based research in five major scientific disciplines: benchmark science, biotechnology, combustion science, fluid physics, and materials science. ATD (Advanced Technology Development) program task descriptions are also included. The bibliography cites the related PI (Principal Investigator) publications and presentations for these program tasks in FY 1994. Three appendices include Table of Acronyms, Guest Investigator Index, and Principal Investigator Index. Derived from text

PROCESS CONTROL OF MICROSTRUCTURE IN MANUFACTURING Final Report, 1 Sep. 1990 - 1 Dec. 1993
Ramana V. Grandhi Jun. 1994 252 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F33615-90-C-5950; AF Proj. 2306)
(AD-A288291; WL-TR-94-4109) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report presents a systematic methodology for the design of optimal process parameters for forging processes. The procedure for construction of a state space model utilizing nonlinear rigid-viscoplastic finite element formulation is developed. A coupled state space model is built to represent the deformation and thermal behavior of the material, with nodal velocities and nodal temperatures as the state variables, and die velocity as input to the system. The output variables of the state space system are the effective strain rate and critical nodal temperature. The linear quadratic regulator (LQR) theory with finite time control is used in designing the ram velocity and initial die temperature. Model reduction schemes are adopted in generating reduced order analytical models from the full size state space representation. The methodology developed is demonstrated on axisymmetric and plane strain forging cases. The performance of the procedure is evaluated using measures such as temperature and strain rate variation within the billet, load requirement, and total process time. DTIC

NONDESTRUCTIVE TESTING APPARATUS FOR DETERMINING THE ORIENTATION OF REINFORCING BARS WITHIN A CONCRETE STRUCTURE Patent
Roman Kruchowy, inventor (to Navy), Dan Goff, inventor (to Navy), and Anthony Smith, inventor (to Navy) 16 Aug. 1994 14 p Filed 17 Dec. 1992
(AD-D017267; US-Patent-5,339,023; US-Patent-Appl-SN-991939;
US-Patent-Class-324-67) Avail: US Patent and Trademark Office

A measuring apparatus which accurately locates reinforcing bars in underwater concrete structures (such as piers, retaining walls, easements and the like) and measures the amount of concrete covering each reinforcing bar. The measuring apparatus comprises a probe which generates a magnetic field and which is moved over the surface of the underwater concrete structure under test When the poles of the magnetic field are in parallel alignment with and directly over a reinforcing bar within the structure a disturbance occurs in the magnetic field with the magnitude of the disturbance being indicative of the depth of concrete covering the reinforcing bar. An electronics module electrically coupled to the probe provides an analog output signal which is indicative of the distance between a reinforcing bar within the concrete structure under test and the probe. This analog signal is supplied to a meter which provides a visual indication of the location of the reinforcing bar and a microprocessor which then calculates the depth of the reinforcing bar within the concrete structure. LAYER COEFFICIENTS FOR NHDOT PAVEMENT MATERIALS
Vincent C. Janoo Sep. 1994 52 p Limited Reproducibility: More than 20% of this document may be affected by poor print and microfiche quality
(AD-A288262; CRREL-SP-94-30) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In 1992, the New Hampshire Department of Transportation (NHDOT) experimented with the use of reclaimed asphalt concrete as a base course material, identified by NHDOT as reclaimed stabilized base (RSB). The RSB and a control test section were placed on Interstate 93 between exits 18 and 19. The RSB test section was designed to the same structural number (SN) as the control. To evaluate the structural capacity of these test sections, the U.S. Army Cold Regions Research and Engineering Laboratory (CRREL) conducted deflection tests using a Dynatest 8000 falling weight deflectometer (FWD). Preliminary analysis of the results by NHDOT personnel showed higher deflection in the reclaimed asphalt concrete test sections. The explanation was that the layer coefficient used for the RSB layer in the design was probably incorrect. A total of 10 test sections constituting the base course materials used by NHDOT were built near Bow, New Hampshire. CRREL evaluated and estimated the layer coefficients of the base course materials. The test program was developed to characterize the material in more than one way. Tests were conducted with the heavy weight deflectometer (HWD), dynamic cone penetrometer (DCP) and the Clegg hammer. In situ California bearing ratio (CBR) tests were also conducted. The deflection from the HWD were used with the WESDEF back calculation program to determine the layer moduli. The moduli were than used with the AASHTO Design Guide to calculate the layer coefficients. The layer coefficients were also determined with the method proposed by Rohde. The CBR values from the Clegg hammer, in situ CBR and DCP tests were also used in the relationships in the HDM model to determine the layer coefficients. DTIC

AIR CUSHIONED LANDING CRAFT (LCAC) BASED SHIP TO SHORE MOVEMENT SIMULATION: A DECISION AID FOR THE AMPHIBIOUS COMMANDER. A (SMMAT) APPLICATION M.S. Thesis
Edward P. Kearns, III Sep. 1994 44 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289635) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Amphibious forces are the enabling force of choice to globally project rapid and sustainable combat power in the littoral. Whether delivering supplies and equipment for military operations or for humanitarian or disaster relief, the air cushioned landing craft (LCAC) is the primary surface ship-to-shore movement craft. The time needed to transfer the forces ashore may be critical to operational success and is an important planning consideration. Many factors complicate accurate prediction of this time. Even so, various commanders must use the best available information, given mission priorities and resource and capability limitations, to make numerous tradeoff decisions in planning and executing the movement of forces. A simulation toolbox, the simulated mobility modeling and analysis toolbox (SMMAT), is introduced, and a robust LCAC ship-to-shore simulation model is developed as an extension to SMMAT. This model provides the commander a prediction and tradeoff analysis tool for planning and executing the projection of power ashore. DTIC

SPRAY-FORMED TOOLING
K. M. McHugh and J. F. Key 1994 6 p Presented at the Society of Automotive Engineers' Convergence '94, Detroit, MI, 18-27 Oct. 1994
(Contracts DE-AC07-76ID-01570; DE-AC07-94ID-13223)
(DE95-005031; EGG-M-94370; CONF-9410256-3) Avail: CASI HC A02/MF A01

The United States Council for Automotive Research (USCAR) has formed a partnership with the Idaho National Engineering Laboratory (INEL) to develop a process for the rapid production of low-cost tooling based on spray forming technology developed at the INEL. Phase 1 of the program will involve bench-scale system development, materials characterization, and process optimization. In Phase 2, prototype systems will be designed, constructed, evaluated, and optimized. Process control and other issues that influence commercialization will be addressed during this phase of the project. Technology transfer to USCAR, or a tooling vendor selected by USCAR, will be accomplished during Phase 3. The approach INEL is using to produce tooling, such as plastic injection molds and stamping dies, combines rapid solidification processing and net-shape materials processing into a single step. A bulk liquid metal is pressure-fed into a de Laval spray nozzle transporting a high velocity, high temperature inert gas. The gas jet disintegrates the metal into fine droplets and deposits them onto a tool pattern made from materials such as plastic, wax, clay, ceramics, and metals. The approach is compatible with solid freeform fabrication techniques such as stereolithography, selective laser sintering, and laminated object manufacturing. Heat is extracted rapidly, in-flight, by convection as the spray jet entrains cool inert gas to produce undercooled and semi-solid droplets. At the pattern, the droplets weld together while replicating the shape and surface features of the pattern. Tool formation is rapid; deposition rates in excess of 1 ton/h have been demonstrated for bench-scale nozzles. DOE

WTEC PANEL REPORT ON RESEARCH SUBMERSIBLES AND UNDERSEA TECHNOLOGIES Final Report
Richard J. Seymore, D. Richard Blidberg, Claude P. Brancart, Larry L. Gentry, Algis N. Kalvaitis, Michael J. Lee, Brad Mooney, and Don Walsh Jun. 1994 342 p Sponsored by NASA, Washington; ARPA; DOE; Dept. of Commerce; DOD; Texas A and M Univ.; Northeastern Univ.; Draper Labs.; Lockheed Missiles and Space Co., Inc.; NOAA; Monterey Bay Aquarium Research Inst.; John B. Mooney, Jr.; and International Maritime, Inc.
(Grant NSF ENG-92-17849)
(NASA-CR-198565; NAS 1.26:198565; ISBN-1-883712-33-5; PB94-184843)
Avail: CASI HC A15/MF A03

This report covers research submersibles and related subsea technologies in Finland, France, Russia, Ukraine and the United Kingdom. Manned, teleoperated, and autonomous submersibles were of interest. The panel found that, in contrast to the United States, Europe is making substantial progress in cooperative and coordinated research in subsea technology, including the development of standards. France is a leader in autonomous vehicle technology. Because much less was known a priori about the technologies in Russia and Ukraine, there were more new findings in those countries than in those Western European nations visited. However, Russia and Ukraine have a sizeable (and currently underutilized) infrastructure in this field, including a highly educated and experienced manpower pool, impressive (in some cases unique) facilities for physical testing, extensive fleets of seagoing research vessels capable of long voyages, and state-of-the-art facilities for conducting oceanographic investigations. The panel visited newly-formed commercial companies associated with long-standing submersible R&D and production centers in Russia and Ukraine. So far, these new efforts are undercapitalized, and as such represent opportunities at very low cost for Western nations, as detailed in the site reports. Author

ALGORITHM TO DESCRIBE THE SPREAD OF A WALL FIRE UNDER A CEILING
H. E. Mitler Nov. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-182259; NISTIR-5547) Avail: CASI HC A04

After some discussion of wall fires, the effects that a ceiling has on a wall fire are analyzed and discussed qualitatively. There are two kinds of effects: first, when the upper sill of the ventilating opening lies below the ceiling (as is usual), a layer of hot gas is trapped, which heats the walls by convection and radiation; the heated ceiling also radiates to the walls. A calculation which uses the wall-fire computer model SPREAD is carried out to demonstrate how these effects can be calculated now. Second, when the flame impinges on the ceiling, it bifurcates and spreads horizontally, rather than vertically. A simple algorithm is presented which calculates the spread rate of these horizontal flame extensions, as well as the modified pyrolysis rate, due to the modified radiation feedbacks. NTIS

A KNOWLEDGE HIGHWAY FOR INTEGRATED MODELLING FROM MANUFACTURING TO DESIGN Final Report, 13 Jan. - 31 Sep. 1994
A. G. Evans 30 Nov. 1994 44 p Prepared in cooperation with Harvard Univ., Cambridge, MA Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0224)
(AD-A288872) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A workshop was held to discuss a new paradigm for choosing the preferred materials and processes needed for manufacturing a component, based on an analysis of the targeted attributes, performance and cost. This paradigm was developed around the idea of a 'knowledge highway'--a disciplined process for generating, storing and using the information most relevant to the manufacturing and design engineers. Model systems were used to develop this idea, which combined many of the technical aspects of greatest concern in manufacturing and design-processing, microstructural evolution, property profiles, fail-safe design, and costing. The concept integrated experimental studies, simulation and analysis. The final result would be software designed to be used by manufacturing and design engineers in selecting materials and processes to meet specific technical/commercial objectives. DTIC

AMCC CASTING DEVELOPMENT. VOLUME 1: EXECUTIVE SUMMARY Final Report
28 Mar. 1995 8 p
(Contract NAS8-39027)
(NASA-CR-196597; NAS 1.26:196597) Avail: CASI HC A02/MF A01

The Advanced Combustion Chamber Casting (AMCC) has been a technically challenging part due to its size, configuration, and alloy type. The height and weight of the wax pattern assembly necessitated the development of a hollow gating system to ensure structural integrity of the shell throughout the investment process. The complexity in the jacket area of the casting required the development of an innovative casting technology that PCC has termed 'TGC' or Thermal Gradient Control. This method, of setting up thermal gradients in the casting during solidification, represents a significant process improvement for PCC and has been successfully implemented on other programs. Metallurgical integrity of the final four castings was very good. Only the areas of the parts that utilized 'TGC Shape & Location System #2' showed any significant areas of microshrinkage when evaluated by non-destructive tests. Alumina oxides detected by FPI on the 'float' surfaces (top sid surfaces of the casting during solidification) of the part were almost entirely less than the acceptance criteria of .032 inches in diameter. Destructive chem mill of the castings was required to determine the effect of the process variables used during the processing of these last four parts (with the exception of the 'Shape & Location of TGC' variable). ASSESSMENT OF LONG-DISTANCE HF RADIO AND SATELLITE COMMUNICATION ASSETS FOR RNLAF OUT-OF-AREA OPERATIONS
R. VanAken, P. J. VanVliet, and P. Ch. Hoefsloot Sep. 1994 78 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A288633; TNO-FEL-94-A200; TDCK-94-0887) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report presents the relative assessment of various long-haul communication systems in order to fulfill the need for communications between the rear area and Royal Netherlands Airforce (RNLAF) units deployed in out-of-area operations. Four different communication systems are compared with respect to the operational aspects: High Frequency (HF) radio communication systems; Military satellite communication (SATCOM) systems; Public access SATCOM systems (such as the INMARSAT system); Private SATCOM networks (based on the use of very small aperture terminals (VSATs)). The comparison is based on the current available communications assets. Future technical developments and their consequences for the system comparison are also discussed. DTIC

SPEECH ANALYSIS AND SYNTHESIS BASED ON PITCH-SYNCHRONOUS SEGMENTATION OF THE SPEECH WAVEFORM Report, 1 Oct. 1992 - 30 Sep. 1993

George S. Kang and Lawrence J. Fransen 9 Nov. 1994 55 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A288824; NRL/FR/5550-94-9743) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes a new speech analysis/synthesis method. This new technique does not attempt to model the human speech production mechanism. Instead, we represent the speech waveform directly in terms of the speech waveform defined in a pitch period. A significant merit of this approach is the complete elimination of pitch interference because each pitch-synchronously segmented waveform does not include a waveform discontinuity. One application of this new speech analysis/synthesis method is the alteration of speech characteristics directly on raw speech. With the increased use of man-made speech in tactical voice message systems and virtual reality environments, such a speech generation tool is highly desirable. Another application is speech encoding operation at low data rates (2400 b/s or less). According to speech intelligibility tests, our new 2400 b/s encoder outperforms the current 2400-b/s LPC. This is also true in noisy environments. Because most tactical platforms are noisy (e.g., helicopter, high-performance aircraft, tank, destroyer), our 2400-b/s speech encoding technique will make tactical voice communication more effective; it will become an indispensable capability for future C4I. MODIFIED GAUSSIAN ELIMINATION FOR ADAPTIVE BEAMFORMING USING RNS ARITHMETIC Final Report, 6 Jul. - 11 Sep. 1992

Barry J. Kirsch and Peter R. Turner (Naval Academy, Annapolis, MD.) 1 Sep. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A288809; NAWCADWAR-94112-50) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper is concerned with the development of a solution to the adaptive beamforming problem. The proposed solution consists of an algorithm-architecture-arithmetic combination which has the potential for very fast solution of the problem on a physically small platform which might be suitable for use on aircraft or sonobuoys. The arithmetic system used in the proposed solution is the RNS system implemented on an array of RNS processors which can be reassigned as the algorithm proceeds. The underlying algorithm is a modification of Gaussian elimination. The (non-RNS) division operations are eliminated in favor of some scaling and the adaptive use of the processor array to accommodate the growth in dynamic range which is implicit in this divisionless implementation. BALANCED DATA FOCUSING: DIRECTION OF ARRIVAL ESTIMATION WITH MAXIMUM LIKELIHOOD PERFORMANCE

William J. L. Read Nov. 1994 55 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A288252; DREO-1233) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The performance of a direction of arrival estimation procedure at low signal-to-noise ratios and limited data samples is an important characteristic. The approach based on maximum likelihood (ML) estimation is considered to be among the best for this problem as long as the underlying signal model is properly chosen. Unfortunately, in most cases, there is no closed-form solution so fast search procedures are employed. Given to a priori knowledge, selecting the initial parameter values for these search procedures can be a difficult problem, especially under low signal-to-noise conditions. In this paper, a new method for uniform linear sensor arrays which overcomes the initial value problem is introduced. This method is called Balanced Data Focusing (BDF). Simulation results are included comparing the performance of this new method to that of the ML approach using the Alternating Projection Maximization search procedure and another popular estimation approach, the root-MUSIC method. METHOD OF PHASED MAGNITUDE CORRELATION USING BINARY SEQUENCES Patent

Michael Pender, inventor (to Navy) 19 Jul. 1994 28 p Filed 15 Nov. 1993

(AD-D017257; US-Patent-5,331,328; US-Patent-Appl-SN-153864; US-Patent-Class-342-189) Avail: US Patent and Trademark Office

This patent discloses a method for allowing a correlation function to be applied to binary codes of length 3 to length 128. A user may specify the desired length of the binary codes for correlation processing; whether the binary code is to use a phase sidelobe level as the threshold or a sidelobe amplitude as the threshold. The user will also be asked to specify the threshold as well as an in phase coefficient referred to as alpha and an out of phase coefficient referred to as a beta. The user may also specify that the codes be expanded which results in correlated compounds having a length twice that of the specified length being displayed to the user. When the user has specified the parameters for correlation processing of the binary code length selected by the user, the program of the present invention will process the binary codes eliminating allomorphic and symmetrical forms of the codes from correlation and then display the results to the user. MULTIPURPOSE BUS INTERFACE UTILIZING A DIGITAL SIGNAL PROCESSOR Patent

Christian L. Houlberg, inventor (to Navy) 20 Sep. 1994 72 p Filed 5 May 1992

(AD-D017264; US-Patent-5,349,685; US-Patent-Appl-SN-878713; US-Patent-Class-395-800) Avail: US Patent and Trademark Office

A multi-purpose bus interface comprising a digital signal processor which receives a clock signal and control signals from a Manchester type encoder/decoder and then processes the clock and control signals allowing for the serial transfer of data to and from the 1553 multiplex data bus, the encoder/decoder and the digital signal processor into an IC memory card for storage in or retrieval from the IC memory card. Software stored in an electrically erasable programmable read only memory controls how the data is transferred and interpreted making it easier to modify the digital signal processor's operation to accommodate its use with different bus standards and data protocols/formats. The encoder/decoder of the present invention formats and protocols data transferred from the electrically erasable programmable read only memory to the 1553 multiplex data bus as well data transferred from the 1553 multiplex data bus to the memory, as appropriate. The multipurpose bus interface of the present invention also includes an RS-232 interface and an RS-422 interface controlled by the digital signal processor which provides for data transfer to and from a host computer or the like into the IC memory card. TARGET DETECTION FOR VISION SYSTEMS Patent
Michael W. Pullen, inventor (to Navy) 2 Aug. 1994 13 p Filed 3 May 1993
(AD-D017271; US-Patent-5,335,297; US-Patent-Appl-SN-055455; US-Patent-Class-395-800) Avail: US Patent and Trademark Office

An autonomous real-time adaptive video target detection and position location apparatus and method. Adaptive low pass filters produce horizontal leading and trailing edge and vertical thresholds from each frame of input target and a background or clutter video signal. A user selectable input is used with the three adaptive thresholds, input video, and horizontal synchronization signal to produce a signal representing valid target detection and position information. EVALUATION OF THE FMICW WAVEFORM IN HF SURFACE RADAR APPLICATIONS
Hing C. Chan Jan. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288245; DREO-1219) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The operation and performance of the Frequency Modulated Interrupted Continuous Wave (FMICW) waveform in ship and aircraft detection using high frequency surface wave radar are analyzed. A modified processing scheme for the FMICW waveform which circumvents the problem of ambiguous range response is presented. The increase in hardware complexity for the modified processing scheme is moderate. The signal-to-clutter ratio and the signal-to-noise ratio are used to evaluate the performance of the FMICW. It is concluded that the FMICW is superior to the simple pulsed waveform in ship-detection application. For aircraft detection, the advantage of the FMICW is marginal. Parameters optimized for ship-detection application will not be optimal for aircraft-detection application because of their much higher velocity which exacerbates the range- walk problem. DTIC

THE ATTENUATION OF MICROWAVE RADIATION BY FOG AND RAIN Final Report
J. D. Pendleton and Stanley Niles Aug. 1994 65 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288326; ARL-TR-527) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In this report, the equations which describe the attenuation of long-wavelength electromagnetic radiation by water fogs and rain are briefly reviewed and explained under the assumption that the aerosol droplets are spherical and that the irradiance of the beam is in the 'linear' regime. Calculations of water fog attenuation coefficients are made using the Rayleigh approximation, and an approximate error analysis of this approximation is made by comparing Rayleigh approximation calculations of absorption efficiency with exact Mie theory calculations of extinction efficiency. Numerical integration of the Mie extinction efficiency is used to compute the attenuation coefficient for rain with a Marshall-Palmer drop size distribution for various rain rates and temperatures. These results are compared with those given by a power law relationship with coefficients given by Olsen, Rogers, and Hodge which was used in the Near Milimeter Wave (NMMW) Module of the Electro- Optical Systems Atmospheric Effects Library (EOSAEL). ELECTROMAGNETIC SPECTRUM OCCUPANCY STUDY OF A POTENTIAL TRANSMITTER SITE FOR THE HF ACTIVE AURORAL RESEARCH PROGRAM (HAARP) Interim Report, May - Jun. 1993
Joseph A. Goldstein, Edward J. Kennedy, and Monroe Y. McGown 30 Sep. 1994 50 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288909; NRL/MR/5554-7622) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The results of measurements conducted by the Naval Research Laboratory in May and June 1993 are presented. The purpose of the measurements was to ascertain the radio frequency occupancy in the immediate vicinity of the proposed High Frequency Active Auroral Research Program (HAARP) facility to be constructed in the Gakona, Alaska area. The HAARP facility will consist of a large planar array of antennas excited by phased high power transmitters operating in the lower portion of the HF band (2.8 to 8 MHz). The existing electromagnetic spectrum usage in the vicinity of Gakona was measured in order to assess the potential for electromagnetic interference problems arising from the HAARP facility. The measurements covered the frequency spectrum from 2 MHz to 1000 MHz. Data was collected for a period of 17 days in May and early June 1993. There are a large number of users in the HF band and data shows a normal diurnal pattern of energy increase in the lower portion of the band in the nighttime hours. The number of users decreases with increasing frequency because the propagation path at higher frequencies is dependent upon line-of-sight signal paths. Gakona is a very rural area and is separated by hilly terrain from surrounding residential and commercial activities. Above the HF bend, the most prominent signal identified is a 152 MHz transient signal that saturates the signal path of our measurement apparatus. The signal is so strong that it produces harmonics throughout the measurement band and distorts the display of the data. Another strong feature that is sometimes observed is a 450 MHz signal. DTIC

AN ACOUSTIC CHARGE TRANSPORT IMAGER FOR HIGH DEFINITION TELEVISION APPLICATIONS Semiannual Status Report, 1 Jan. 1994 - 31 Mar. 1995
W. D. Hunt and Kevin F. Brennan Oct. 1994 162 p Sponsored in part by NSF and ARPA

(Contract NAGw-2753; E21-H36)
(NASA-CR-197841; NAS 1.26:197841) Avail: CASI HC A08/MF A02

The primary goal of this research is to develop a solid-state high definition television (HDTV) imager chip operating at a frame rate of about 170 frames/sec at 2 Megapixels per frame. This imager offers an order of magnitude improvement in speed over CCD designs and will allow for monolithic imagers operating from the IR to the UV. The technical approach of the project focuses on the development of the three basic components of the imager and their integration. The imager chip can be divided into three distinct components: (1) image capture via an array of avalanche photodiodes (APD's), (2) charge collection, storage and overflow control via a charge transfer transistor device (CTD), and (3) charge readout via an array of acoustic charge transport (ACT) channels. The use of APD's allows for front end gain at low noise and low operating voltages while the ACT readout enables concomitant high speed and high charge transfer efficiency. Currently work is progressing towards the development of manufacturable designs for each of these component devices. In addition to the development of each of the three distinct components, work towards their integration is also progressing. The component designs are considered not only to meet individual specifications but to provide overall system level performance suitable for HDTV operation upon integration. The ultimate manufacturability and reliability of the chip constrains the design as well. The progress made during this period is described in detail in Sections 2-4. Derived from text

SPACE TETHER-RADAR DATA PROCESSING M.S. Thesis
Wayne A. Brewster Sep. 1994 81 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289654) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

NASA conducted the Delta-PMG tethered satellite mission. It was conducted to verify the hollow cathode plasma source's ability to couple electric currents from each end of a long wire tether traversing the ambient low earth orbit ionosphere plasma. Observations were obtained through a suite of sensors which included large ground based VHF radars. The goal of this thesis was to process the radar data received at the radar based in Hawaii to study disturbances in the earth's ionosphere caused by the tether. After extensive analysis, unique radar returns were identified that were associated with the passage of the tether system through magnetic field lines threading the radar's field of view. These returns were interpreted as a plasma cloud propagating along a magnetic field line and reflecting back along another. This phenomenon produced dual returns with inverted Doppler frequency content. DTIC

REDUCTION OF OFF-BORESIGHT FIELDS FOR A TEM HORN ANTENNA M.S. Thesis
Dennis J. Wolstenholme Dec. 1994 173 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289708; AFIT/GE/ENG/94D-33) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research involves the design, modeling, and testing of both tapered periodic surfaces (TPS) and transverse electromagnetic (TEM) horns. The goal is to reduce the off-boresight fields for a TEM horn and increase the peak-to-peak field levels on boresight. This is accomplished by applying a TPS to the free space end. Two tapers are designed - one that approximates an exponential impedance function and one that approximates a triangular impedance function. Both reduce the off-boresight fields of the TEM horn. In most cases the exponential taper reduces the field levels further than the triangular taper. This research shows that a TPS is an effective method of reducing diffraction. A procedure for designing a TPS to approximate a specific impedance function is presented. A two-dimensional finite difference time domain (FDTD) model predicts the tapers will reduce the diffraction. Experimental results verify the TPS's ability to reduce the peak off-boresight fields for a TEM horn antenna. DTIC

COMPUTATION OF ELECTROMAGNETIC SCATTERING PARAMETERS FOR LOGNORMAL DISTRIBUTIONS OF MAGNETIC SPHERES: THEORY AND ALGORITHMS Final Report, Jan. 1991 - Jan. 1994
Merrill E. Milham Oct. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 1O1-62622-A-552)
(AD-A289672; ERDEC-TR-212) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In this report, relevant parts of the scattering theory for magnetic spheres are presented. Mass extinction coefficients, and the lognormal size distribution are defined. The theory and algorithms for integrating scattering parameters over size distributions are developed. The integrations are carried out in terms of dimensionless scattering, and size distribution parameters, which are simply related to the usual mass scattering coefficients. Fortran codes, which implement the algorithmic design, are presented, and examples of code use are given. Code listings are included. DTIC

THE AUTOMATIC EXTRACTION OF SELECTED SPEECH SPECTRAL CHARACTERISTICS [AUTOMATYCZNA EKSTRAKCJA WYBRANYCH CECH WIDMOWYCH MOWY]
Henryk Kubzdela 1994 20 p In POLISH
(ISSN 0208-5658)
(IFTR-2/1994) Avail: Issuing Activity (Polish Academy of Sciences, Warsaw, Poland)

The operation of automatic segmentation of a speech signal into basic phones is an especially difficult aspect of modelling the process of decoding the information contained in speech. Spectral characteristics which characterize the spectrographic patterns of different speech sounds should be used as the basis for this segmentation. Unfortunately, speech signals have properties which make it difficult to extract these characteristics. The imperfection of digital acoustic signal analysis also causes problems. The author assumed that the distinctive spectral characteristics of a sound are primarily contained in the level and frequency of the strongest component and the components occurring in the vicinity of points of the amplitude spectrum indicated by the positions of the extrema of a function (FMOW) which models the envelope of the spectrum. A discrete pattern of this function can be obtained by two-step equalizing transformation of the peaks of the amplitude spectrum. The author uses examples to illustrate the results of procedures for determining the intervals of convexities, concavities, and extrema of the FMOW function. The author also provides examples which illustrate the segmentation values of the information contained in time curves of the level of the spectrum at the points indicated by the peaks of the FMOW function. AN EXPERIMENTAL VERSION OF THE MZT (SPEECH-FROM-TEXT) SYSTEM WITH EXTERNAL F(SUB 0) CONTROL [WERSJA EKSPERYMENTALNA SYSTEMU MZT (MOWY Z TEKSTU) Z ZEWNETRZNYM STEROWANIEM FO]
Ignacy Nowak Cooperative Publishing House Ltd. 1994 29 p In POLISH
(ISSN 0208-5658)
(IFTR-14/1994) Avail: Issuing Activity

The version of a Polish speech from text system described in this article was developed using the speech-from-text system. The new system has additional functions which make it possible to enter commands in edited orthographic text to control the phrase component and accentuation parameters. This makes it possible to generate a series of modified intonation contours in the texts spoken by the system. The effects obtained are made easier to control by a graphic illustration of the base frequency pattern in phrases that were last 'spoken' by the system. This version of the system was designed as a test prototype which will help us expand and refine our set of rules for automatic generation of intonation contours, which in turn will enable the fully automated speech-from-text system to generate speech with a more varied and precisely formed fundamental frequency pattern. PERCEPTUAL BASED IMAGE FUSION WITH APPLICATIONS TO HYPERSPECTRAL IMAGE DATA M.S. Thesis

Terry A. Wilson Dec. 1994 213 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289429; AFIT/GE/ENG/94D-32) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Development of new imaging sensors has created a need for image processing techniques that can fuse images from different sensors or multiple images produced by the same sensor. The methods presented here focus on combining image data from the Airborne Visual and Infrared Imaging Spectrometer (AVIRIS) hyperspectral sensor into a single or smaller subset of images while maintaining the visual information necessary for human analysis. Three hierarchical multi-resolution image fusion techniques are implemented and tested using the AVIRIS image data and test images that contain various levels of correlated or uncorrelated noise. Two of the algorithms are published fusion methods that combine images from multiple sensors. The third method was developed to fuse any co-registered image data. This new method uses the spatial frequency response (contrast sensitivity) of the human visual system to determine which parts of the input images contain the salient features that need to be preserved in the composite image(s). After analyzing the signal-to-noise ratios and visual aesthetics of the fused images, contrast sensitivity based fusion is shown to provide excellent fusion results and, in every case, clearly outperformed the other two methods. Finally, as an illustrative example of how the fusion techniques are independent of the hyperspectral application, they are applied to fusing multiple polarimetric images from a Synthetic Aperture Radar to enhance automated targeting techniques. A 3-D FINITE DIFFERENCE TIME DOMAIN INVESTIGATION OF MICROWAVE PROPAGATION THROUGH INHOMOGENEOUS BIOLOGICAL MATERIALS M.S. Thesis

David B. Dunn, Jr. Dec. 1994 158 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289431; AFIT/GE/ENG/94D-05) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper extends past analysis of an optimal source distribution around a homogeneous sphere of muscle tissue by using a 3-D finite difference time domain (FDTD) scenario in which an anatomically correct human head model is irradiated. It first duplicates the analytical solution within an FDTD space using an FDTD computer code developed at Penn State University. This duplication uses a 9.45 cm radius sphere represented in an FDTD space of 2.35 mm cubic cells. FDTD simulations are then performed on four, three, and two layer laminated spheres, designed to provide simple models of a head. Finally, four simulations were performed in FDTD on the human head model developed at Penn State from an MRI scan of an actual human head. The comparison of analytic simulations to the FDTD simulations on a homogeneous sphere showed a pixel by pixel average of 5.34% error between the two with a standard deviation of 7.84%. The layered sphere models showed considerable spiking at the two poles along with a small amount of spiking due to the stair-step approximation of the spheres. None of these spikes increased the power beyond that at the surface and hence were not critical. The simulations on a true human head showed improvement in depth due to the low-loss of the bone tissue. This study demonstrates that microwave hyperthermia with good resolution is possible in an anatomically correct head model. DTIC

THE AMBIGUITY FUNCTION OF THE STEPPED FREQUENCY RADAR Final Report

Jen-Chih Huang Sep. 1994 97 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289533) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

High range resolution radar systems have many advantages such as target classification, resolution of multiple target, accurate range profile, and detection of low radar cross section (RCS) targets in clutter. High range resolution requires large bandwidths. Stepped frequency waveforms can achieve high range resolution by increasing the effective bandwidth without increasing the instantaneous bandwidth which would increase the hardware requirements including higher analog to digital (A/D) sampling rates which are limited by existing technology. Under today's hardware limitations, the stepped frequency waveform becomes very important. This thesis briefly discusses the stepped frequency radar and associated signal processing; it investigates the ambiguity function of the stepped frequency waveform and the stepped frequency radar system. Mathematical expressions of ambiguity functions are derived and the improvement of clutter suppression capability for the stepped frequency radar by rejecting initial pulses is also discussed. DTIC

CLASSIFICATION OF ULTRA HIGH RANGE RESOLUTION RADAR USING DECISION BOUNDARY ANALYSIS M.S. Thesis

Christopher L. Eisenbies Dec. 1994 122 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289378; AFIT/GE/ENG/94D-07) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis examines the discrimination of targets with Ultra High Range Resolution (UHRR) radar data. Using these measured signals from frontal aspect angles of four aircraft classes, the baseline performance of the Adaptive Gaussian Classifier (AGC) is tested with respect to aligning exemplars to templates. Alignment plays a crucial role in the AGC's classification performance which can degrade by 11% for a target class. The AGC is compared to non-parametric classifiers, but no statistically significant degradation of performance is found. Data separability is analyzed by hounding the Bayes error. The data is well separated in a statistical sense. A feature selection algorithm based on analysis of the decision boundary, is applied to find a reduced feature set, which are linear combinations of the original features. These features are optimized with respect to classification error rather than reconstruction error. This technique is extended to deduce the relevant features in the original feature space. Fewer than 5% of the features in the original feature space may be used to attain an improved classification rate. This new method is a true reduction of features and shows improvement up to 15%. Discrimination of UHRR radar signatures using a multiresolution analysis is proposed. The decision boundary analysis chooses relevant wavelet scales with respect to classification. Some improved performance against an entropy based measure is observed for limited feature sets. The technique developed here successfully chooses the scale that causes classification performance to peak within 5% of the performance in the full-dimensional or reduced-dimensional UHRR radar signature space. IMPROVING THE PERFORMANCE OF SPIRAL ANTENNAS BY USING PASSIVE SCATTERERS Final Report

Joseph S. Zaren Dec. 1994 349 p Limited Reproducibility: More than

20% of this document may be affected by microfiche quality
(AD-A289324; AFIT/GE/ENG/94D-34) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this study was to explore the viability of improving the performance of cavity-backed antennas. Traditionally antenna cavities are filled with electromagnetic absorber to mitigate interference effects that would otherwise cause the antenna radiation pattern to vary widely at different frequencies. The approach used in this research was to replace the absorber with dielectric slabs, some of which contained arrays of dipoles. These dipole arrays were modeled as frequency selective surfaces using two periodic moment method based - computer programs and one transmission line program. A systematic study was performed that identified the effect of changing the dipole array parameters on prospective cavity designs. Seven different cavity configurations were tested using a log periodic trapezoid wire antenna system designed to support 2.3-12.4 0Hz. Cavity configurations using one, two, and three layers of dipole arrays were tested and compared to both absorber-filled and dielectric-filled cavity configurations. The results were inconclusive because even though some two layer designs and one three layer design had better gain almost entirely throughout the 2-12 GHz region, the gain of the baseline absorber-filled and dielectric-filled cavities varied widely over this bandwidth. No cavity condition provided an extended 3 dB bandwidth. Additional research is recommended. DTIC

PREDICTION OF RAIN ATTENUATION AND TOTAL ATMOSPHERIC ATTENUATION FOR LOW-AVAILABILITY SATELLITE COMMUNICATIONS IN EUROPE

S. Karhu and E. Salonen Aug. 1994 58 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-184925; ISBN-951-22-2144-6) Avail: CASI HC A04

Attenuation models for oxygen, water vapor, clouds, and rainfall, as well as the meteorological data from the ECMWF (the European Centre for Medium-Range Weather Forecasts), are outlined in order to predict the average annual distributions of the total atmospheric attenuation at 10-50 GHz for Europe. The distributions are intended for the design of low-availability satellite communication systems operating at the outage time greater than 0.1% of the year. The fair weather attenuation due to oxygen, water vapor, and clouds is calculated for a specified frequency, site, and elevation angle from the distributions at 12, 20, 30, 40, and 50 GHz, determined in the zenith direction from the time series of the ECMWF grid data. The methods are introduced for the scaling of the frequency and the altitude, for the interpolation in the horizontal direction, and for the scaling of the elevation angle. The distribution of the total atmospheric attenuation is determined on the equiprobability basis from the distributions of the fair weather attenuation and rain attenuation. The models and data are tested in three ways at the annual outage percentage range of 0.1-10% by comparing 23 predicted and measured attenuation distributions of 11.4-30 GHz from eight European sites. INFORMATION SUPERHIGHWAY: ISSUES AFFECTING DEVELOPMENT

Sep. 1994 77 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289434; GAO/RCED-94-285) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Technological advances in the transmission of voice, video, and data are fostering fundamental changes in the telecommunications industry. For example, large local telephone companies plan to offer video services in competition with cable and broadcast television, while cable television companies plan to offer local telephone service over their wires in competition with the local telephone companies. The administration believes that these technological changes provide the opportunity to develop an 'Information Superhighway' that could provide every element of society with ready access to data, voice, and video communications. Concurrently, the Congress is considering sweeping changes to telecommunications regulations to keep pace with this dynamic industry. GAO prepared this report to serve as an overview of three key issues that decisionmakers may face as they deliberate telecommunications legislation; it focuses on three pivotal issues they face in formulating new telecommunications legislation: (1) managing the transition to a more competitive local telecommunications marketplace; (2) ensuring that all consumers have access to affordable telecommunications as competition develops; and (3) ensuring that the Information Superhighway provides adequate security, privacy, reliability, and interoperability. Integration of a solid-state transistor oscillator with a radiative element has many advantages: it eliminates the feed network; replaces the expensive waveguide transition; reduces the size of the antenna system; and provides active impedance matching. Active devices also offer promise for optical control of beam steering antenna arrays. The objective of this thesis is to determine the physical characteristics of an active antenna and understand its operational principles. DTIC

MILESTONES IN TELECOMMUNICATIONS IN SOME SELECTED COUNTRIES

K. Kivinen Oct. 1994 64 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-184826; ISBN-951-22-2291-4) Avail: CASI HC A04

The publication presents an overall picture of the development of telecommunications in the United States, the United Kingdom, Sweden, and Finland. Modern telecommunications, as we see it today, is a result of work done and decisions made in several fields such as basic research, component technology, the needs of business and households, general attitudes towards telecommunications during periods of peace and during wars, questions of 'natural monopoly' and market economy. The book acknowledges this fact and thus deals with more than the development of the technology. It follows as strict as possible a chronological order, so that chains of events can be followed up. The book is a compilation of facts found in different sources. NTIS

POLARIZATION SENSITIVITY OF MONOPULSE RADAR BORESIGHT ERROR INDUCED BY LARGE, OGIVE RADOMES M.S. Thesis

Kelce S. Wilson Dec. 1994 91 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289254; AFIT/GE/ENG/94D-31) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The dependence of Boresight Error (BSE) on incident Electric Field (E-Field) polarization tilt angle is investigated. BSE, defined as the angular difference between a target's actual and radar-indicated position, is influenced by the radome used to protect the antenna. A reliable computer model for predicting the BSE of electrically large radar-radome systems has been demonstrated and used to investigate the dependence of radome-induced BSE for various combinations of scan angle, element polarization, and incident E-Field polarization. The analysis includes a development of a transmission/depolarization model to justify the results of the computer model. Results compare very well with empirical, published, and experimentally measured data for specific scan angle and polarization cases considered. Generally, BSE exhibits a noticeable dependence on E-Field polarization, except under limited scanning conditions for specific linearly polarized antenna apertures. DTIC

PROCESSING OF WIDE-ANGLE SYNTHETIC APERTURE RADAR SIGNALS FOR DETECTION OF OBSCURED GROUND TARGETS M.S. Thesis

Richard J. Sumner Dec. 1994 79 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289243; AFIT/GE/ENG/94D-28) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis investigates advanced processing techniques for the detection of radar targets in the presence of clutter. It is assumed that the radar data available consist of multi-aspect angle, fully polarimetric Synthetic Aperture Radar (SAR) images. Various techniques are introduced and tested on available SAR data. These techniques attempt to exploit the multi-aspect angles in order to extract target characteristics not available in any single image. SAR images are manipulated in such a way to decrease the probability of false alarms in the target detection process. Target detection performance of the techniques is presented and compared. The techniques are shown to give superior results than that of regular SAR. DTIC

ON-AXIS POLARIZATION COUPLING IN y-CUT TITANIUM IN-DIFFUSED LITHIUM NIOBATE SLAB WAVEGUIDES Technical Report

Stephen L. Kwiatkowski, Alan R. Mickelson, and Dag R. Hjelme Oct. 1994 42 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1190)
(AD-A289260; ECE/GWOL/65) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We report on polarization coupling from x-propagating TE-polarized waveguide modes to TM-polarized radiation modes in y-cut titanium in-diffused lithium niobate slab waveguides. The polarization coupling is linear with respect to the TE-polarized input power and depends on the titanium diffusion time. Furthermore, the polarization coupling was not affected by white light flooding the waveguide. The maximum conversion from a TE-polarized waveguide mode to a TM-polarized radiation mode is 3.2%/cm using a conservative estimate for the power initially in the TE waveguide mode. We observe no turn-on delay greater than 1 s between the excitation of the TE waveguide mode and the observation of the TM radiation. In addition, intentional amplitude modulations of the TE-polarized waveguide mode were registered as equivalent amplitude modulations by the TM-polarized radiation modes. We did not observe polarization coupling from x-propagating TM-polarized waveguide modes to TE-polarized radiation modes. DTIC

(AF Proj. 2311)
(AD-A289277; PL-TR-94-2308) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We discuss two different techniques for the comparison of polarization signal in magnetic fields, the calibration curves and derivative methods, for the case of an imaging magnetograph. The advantages and typical errors of both techniques are analyzed in respect to the instrumental characteristics, particularly the spectral response. Both methods present high degree of errors, but the calibration curves method is probably more suitable for the present instrumental configuration of the SVMG. DTIC

MULTIPOINT MULTIRATE SIGNAL PROCESSING M.S. Thesis

Roger L. Claypoole, Jr. Dec. 1994 93 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289211; AFIT/GE/ENG/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis provides a fundamentally new, systematic study of multipoint multirate signal processing systems. The multipoint multirate operators are analyzed via equivalent circuits comprised entirely of conventional multirate operators. Interconnections of the operators are demonstrated, and the multipoint noble identities are derived. The multipoint polyphase representation is presented, and the M channel multipoint multirate system with vector length N is presented as an MN channel multipoint polyphase system. The conditions sufficient for perfect reconstruction in the multipoint multirate system are derived. These conditions constrain the multipoint filter banks to be composed of comb filters generated from paraunitary sets of conventional filters. The perfect reconstruction multipoint multirate system is then combined with the multiresolution wavelet decomposition to form the generalized wavelet decomposition with varying vector decimation length at each level. The generalized wavelet decomposition is used as an algorithm to redistribute the energy of a signal throughout the levels of the decomposition. It is shown that, for band pass and high pass signals, significant improvements can be made in the energy distribution. It is recommended that this algorithm be studied as a front end to a vector quantizer for data compression applications. DTIC

A synoptic data collection effort was begun using the East Coast Radar System (ECRS), as part of Air Force investigations of equatorial ionospheric clutter. Due to the volume of data, an automatic processing scheme has been developed to characterize radar Doppler frequency spectra in terms of a small number of parameters. These parameters allow reconstruction of reasonable facsimiles of the original spectra, and facilitate a comprehensive statistical analysis. A data compression algorithm has also been implemented to provide smoothing and further data reduction. This report describes the compression and processing algorithms, and presents some results from the January, 1992 data campaign. DTIC

VOCAR: AN EXPERIMENT IN VARIABILITY OF COASTAL ATMOSPHERIC REFRACTIVITY

Richard A. Paulus Oct. 1994 5 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289202) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A previous radio-meteorological experiment conducted along the coast of southern California showed a high correlation between UHF signals and the base of the elevated temperature inversion. A reanalysis of this experimental data with a recently developed hybrid propagation model confirmed this correlation and a method to remotely sense the refractive structure was proposed. An experiment called Variability of Coastal Atmospheric Refractivity (VOCAR) was designed under a larger program called Coastal Variability Analysis, Measurements, and Prediction. VOCAR is a multi-year experimental effort to investigate the variability of atmospheric refractivity with emphasis on the coastal zone. The experiment is being conducted by the Naval Command, Control and Ocean Surveillance Center RDT&E Division jointly with the Naval Air Warfare Center Weapons Division, Point Mugu, CA, the Naval Research Laboratory (Washington, DC and Monterey), and the Naval Postgraduate School. In addition, the National Oceanic and Atmospheric Administration Environmental Technology Laboratory, Penn State University Applied Research Laboratory and Johns Hopkins University Applied Physics Laboratory participated in the intensive measurement phase of VOCAR. The objectives of VOCAR are to provide an assessment capability for horizontally varying refractivity conditions in a coastal environment and to develop a remote sensing capability. The propagation measurements being made during VOCAR consist of monitoring signal strength variations of VHF/UHF transmitters in the southern California coastal region. Corresponding meteorological measurements are made during routine, special, and intensive observation periods. Measurements began in May 1993 and will be conducted periodically through 1994. DTIC

VOICE ANALYSIS USING THE BISPECTRUM M.S. Thesis
Deborah A. Douglass Dec. 1994 73 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289204; AFIT/GSO/ENG/94D-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The theory of the bispectrum has been studied, though very few practical applications have yet been considered in any depth. One application mentioned in the literature is the use of the bispectrum for voice signal processing. The aim of this thesis was to research the bispectrum towards the particular application of speech enhancement. The technique is based on the fact that the bispectrum is zero for a Gaussian white noise signal, and the bispectrum of two signals added together is the sum of the two signal bispectra. Theoretically, processing signals in the bispectra domain should increase the signal-to-noise ratio of the speech signal. The signal can then be reconstructed from the bispectrum. Though the theory of the estimation techniques were proven, the applicability of the bispectrum to voice processing was questionable. Since any additive white noise is a random process, it will only be the expected value that is zero. With speech signal, the signal is considered stationary for only approximately 20 milliseconds. This does not allow a significant amount of the noise energy to be removed through the averaging process. Classical methods are just as effective. DTIC

ADAPTIVE BEAMFORMING IN FREQUENCY-DISPERSIVE MULTIPATH ENVIRONMENTS M.S. Thesis
David A. Murray Dec. 1994 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289206; AFIT/GE/ENG/94D-22) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

It is well known that an antenna array with N degrees of freedom (DOF) can cancel N - 1 interferers if they approach the array from directions other than that of the desired signal. It has been shown that there are cases in which it is possible for an array with N DOF to effectively cancel more than N - 1 interferers. Specifically, we show how this can be done when there is incident upon an N-element array not only the desired signal and a jammer signal, but more than N - 1 Doppler-shifted multipath copies of the jammer signal as well. In this situation the received signal is nonstationary; therefore, updates of the weight vector must use only as many samples as those which correspond to the time interval over which the signal can be considered locally stationary. In this frequency-dispersive environment, it is desirable to recalculate the weight vector often; in some cases, we would like to do so with every sample. However, recalculating the weight vector involves estimating and inverting the covariance matrix of the received signal. Using traditional methods, this is an O(N sup 3) process, where N represents the degrees of freedom in the array. For large N this becomes time-prohibitive. In this paper, the authors examine the application of eigenvalue decomposition and rank-one updating of the covariance matrix to reduce the computation required. By exploiting the structure of the matrix they find that they are able to decrease the time required for its estimation and inversion. Using these techniques, they can update the weight vector every sample, enabling them to operate effectively in a frequency-dispersive environment. DTIC

MODELING SURFACE EFFECTS WITH THE PARABOLIC EQUATION METHOD
Herbert V. Hitney Oct. 1994 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289199) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An approximate but efficient technique is presented that accounts for vertical polarization and rough surface effects over the sea for ducting conditions using the split-step, parabolic equation method. The primary justification for this semi-empirical technique is that in most cases propagation loss predictions match results from a waveguide model that is believed to account for these effects properly. The technique and comparisons of modeled results versus waveguide results and measured data are examined. DTIC

SIMPLE EQUIVALENT DIPOLE DISTRIBUTIONS FOR DIELECTRIC SPHEROIDAL SCATTERERS
J. C. E. Sten Oct. 1994 14 p
(PB95-184883; ISBN-951-22-2322-8) Avail: CASI HC A03/MF A01

Equivalent source distributions are identified for dielectric spheroids when immersed in a homogeneous electrostatic field. It is shown that for a prolate spheroid, the volume polarization shrinks into a line dipole distribution lying between the foci of the spheroid. The equivalent charge distributions responsible for the field scattered by an oblate spheroid arise on the circular disk of focal radius. The solutions give rise to an alternative way of calculating electromagnetic fields near spheroidal particles in the regime of the quasi-static approximation. NTIS

ISOLATED DIGIT RECOGNITION WITHOUT TIME ALIGNMENT M.S. Thesis
Jeffrey Mark Gay Dec. 1994 148 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289344; AFIT/GE/ENG/94D-12) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis examines methods for isolated digit recognition without using time alignment. Resource requirements for isolated word recognizers that use time alignment can become prohibitively large as the vocabulary to be classified grows. Thus, methods capable of achieving recognition rates comparable to those obtained with current methods using these techniques are needed. The goals of this research are to find feature sets for speech recognition that perform well without using time alignment, and to identify classifiers that provide good performance with these features. Using the digits from the TI46 database, baseline speaker-independent recognition rates of 95.2% for the complete speaker set and 98.1% for the male speaker set are established using dynamic time warping (DTW). This work begins with features derived from spectrograms of each digit. Based on a critical band frequency scale covering the telephone bandwidth (300-3000 Hz), these critical band energy features are classified alone and in combination with several other feature sets, with several different classifiers. With this method, there is one 'short' feature vector per word. For speaker-independent recognition using the complete speaker set and a multi-layer perceptron (MLP) classifier, a recognition rate of 92.4% is achieved. For the same classifier with the male speaker set, a recognition rate of 97.1% is achieved. For the male speaker set, there is no statistical difference between results using DTW, and those using the MLP and no time alignment. This shows that there are feature sets that may provide high recognition rates for isolated word recognition without the need for time alignment. DTIC

MULTICLASSIFIER FUSION OF AN ULTRASONIC LIP READER IN AUTOMATIC SPEECH RECOGNITION M.S. Thesis
David L. Jennnings Dec. 1994 100 p Limited Reproducibility: More

than 20% of this document may be affected by microfiche quality
(AD-A289207; AFIT/GE/ENG/94D-16) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis investigates the use of two active ultrasonic devices in collecting lip information for performing and enhancing automatic speech recognition. The two devices explored are called the 'Ultrasonic Mike' and the 'Lip Lock Loop.' The devices are tested in a speaker dependent isolated word recognition task with a vocabulary consisting of the spoken digits from zero to nine. Two automatic lip readers are designed and tested based on the output of the ultrasonic devices. The automatic lip readers use template matching and dynamic time warping to determine the best candidate for a given test utterance. The automatic lip readers alone achieve accuracies of 65-89%, depending on the number of reference templates used. Next the automatic lip reader is combined with a conventional automatic speech recognizer. Both classifier level fusion and feature level fusion are investigated. Feature fusion is based on combining the feature vectors prior to dynamic time warping. Classifier fusion is based on a pseudo probability mass function derived from the dynamic time warping distances. The combined systems are tested with various levels of acoustic noise added. In one typical test, at a signal to noise ratio of 0dB, the acoustic recognizer's accuracy alone was 78%, the automatic lip reader's accuracy was 69%, but the combined accuracy was 93%. This experiment demonstrates that a simple ultrasonic lip motion detector, that has an output data rate 12,500 times less than a typical video camera, can significantly improve the accuracy of automatic speech recognition in noise. A DEMONSTRATION OF CLIENT-SERVER TECHNOLOGY USING REMOTE PROCEDURE CALLS WITH AN APPLICATION IN FILE MIGRATION USING HEURISTICS

Eric DeLange Dec. 1994 69 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289467; AFIT/CI/CIA/94-144) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Client/Server technology is one of the fastest growing areas of interest and research in the computer field. Remote Procedure Calling (RPC) is a popular framework for programming in a distributed client/server environment since it facilitates communication between machines operating on different platforms and resembles traditional programming methodologies. This paper first explores the fundamental concepts behind the implementation of RPC programming. Once a basic explanation of the RPC concept is given, a small example program is illustrated in order to highlight essential elements in any RPC program. A discussion of RPC's applicability in the area of file migration ensues. Specifically, the utility of RPC in automatically migrating files according to specific rules is examined, such as when a file has been accessed a predetermined number of times from a remote source. An explanation of some of the features of a program developed by the author (in conjunction with others named in the Preface) then follows. Finally, a way to provide a front end in the HP-UX workspace environment is presented after which the author reviews the lessons learned from and possible amplifications to the project. A bibliography and appendices containing code to the RPC applications are also provided. DTIC

NONLINEAR SIGNAL PROCESSING SCHEMES FOR ROBUST TARGET DETECTION IN RADAR Final Technical Report, 1 Jul. 1992 - 30 Sep. 1994

Nihat M. Bilgutay and Jafar Saniie (Illinois Inst. of Tech., Chicago, IL.) 28 Nov. 1994 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-1735)
(AD-A288449) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In detection, the interference due to clutter or jamming can severely deteriorate the quality of the received signal to the point of concealing the target. The objective of this investigation is to improve detection in high density clutter or jamming by using nonlinear signal processing in conjunction with frequency diverse techniques. In particular, analysis and experimental studies have been concerned with the application of Order Statistic (OS) processing and Split Spectrum Processing (SSP) to detect target signals corrupted by strong clutter. The study of OS processing is also extended to morphological processors to improve signal-to-noise ratio (SNR) and feature extraction for recognition and classification. These studies have applications in radar, ultrasound, sonar, and imaging where clutter is the primary limiting factor. DTIC

THE EVOLUTION AND IMPACT OF PCS TECHNOLOGY Final Report

John R. Lawson Sep. 1994 49 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288606; IDA-D-1595) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In today's mobile society, communications services that focus on location (wired) are increasingly inadequate. But services that center around the individual (wireless) are being developed to serve society in a way that only recently could consumers have imagined. People-oriented communications tools will make life simpler and more productive. The essence of this concept is captured in a family of wireless services and devices that allow the user to communicate independent of location--Personal Communications Services, known as PCS. First generation PCS devices such a pagers and cellular phones were the instruments of the first wireless revolution, but they will soon be forced to relinquish the spotlight to the new generation of PCS and what should be a dazzling variety of individualized advanced telecommunications services and devices. Within the next two years, these new PCS models, recently described as 'the most exciting development in telecommunications since the breakup of AT&T,' should hit the marketplace, changing the way we communicate and, in turn, the way we live. This paper explores the status and likely development of PCS generally, including 'new PCS.' DTIC

LANDAU QUASI-ENERGY SPECTRUM DESTRUCTION FOR AN ELECTRON IN BOTH A STATIC MAGNETIC FIELD AND A RESONANT ELECTROMAGNETIC WAVE

A. A. Skoblin 1994 6 p
(DE95-610176; JINR-E-4-94-176) Avail: CASI HC A02/MF A01 (US Sales Only)

Free. nonrelativistic electrons in both a static magnetic field and an electromagnetic wave are considered. A plane-polarized wave propagates along a magnetic field; its frequency is close to the electron rotation frequency in a magnetic field. Electron spin is taken into account. An electron quasi energy spectrum and steady states (quasi energy states) are constructed. DOE

CLASSIFICATION OF RF TRANSIENTS IN SPACE USING DIGITAL SIGNAL PROCESSING AND NEURAL NETWORK TECHNIQUES

K. R. Moore, P. C. Blain, S. D. Briles, and R. G. Jones 1995 11 p Presented at the SPIE International Symposium on Aerospace/Defense Sensing and Dual-Use Photonics, Orlando, FL, 17-21 Apr. 1995 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE95-006287; LA-UR-95-413; CONF-950472-1) Avail: CASI HC A03

The FORTE' (Fast On-Orbit Recording of Transient Events) small satellite experiment scheduled for launch in October, 1995, will attempt to measure and classify electromagnetic transients as sensed from space. The FORTE' payload will employ an event classifier to perform onboard classification of radio frequency transients from terrestrial sources such as lightning. These transients are often dominated by a constantly changing assortment of man-made 'clutter' such as TV, FM, and radar signals. The FORTE' event classifier, or EC, uses specialized hardware to implement various signal processing and neural network algorithms. The resulting system can process and classify digitized records of several thousand samples onboard the spacecraft at rates of about a second per record. In addition to reducing downlink rates, the EC minimizes command uplink data by normally using uploaded algorithm sequences rather than full code modules (although it is possible for full code modules to be uploaded from the ground). The FORTE' event classifier experiment combines science and engineering in an evolutionary step toward useful and robust adaptive processing systems in space. DOE

AN INTRODUCTION TO WAVELET TRANSFORMS

P. P. Vaidyanathan and Igor Djokovic Aug. 1994 121 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-93-1-0231)
(AD-A289083) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

These notes are meant to provide an introduction to wavelet transforms. The first five sections can be accessed by readers with some exposure to signal processing tools. While maintaining a mathematically rigorous presentation level, we have attempted to make the presentation accessible to signal processors, and engineers in general. To make this possible, we have included three review sections on mathematics, especially L(1) and L(2) Fourier transforms. Derived from text

SHEAR ALFVEN WAVE EXCITATION BY DIRECT ANTENNA COUPLING AND FAST WAVE RESONANT MODE CONVERSION

G. G. Borg 1994 26 p
(DE95-609109; ANU-PRL-TR-94/1) Avail: CASI HC A03/MF A01 (US Sales Only)

Antenna coupling to the shear Alfven wave by both direct excitation and fast wave resonant mode conversion is modelled analytically for a plasma with a one dimensional linear density gradient. We demonstrate the existence of a shear Alfven mode excited directly by the antenna. For localized antennas, this mode propagates as a guided beam along the steady magnetic field lines intersecting the antenna. Shear Alfven wave excitation by resonant mode conversion of a fast wave near the Alfven resonance layer is also demonstrated and we prove that energy is conserved in this process. We compare the efficiency of these two mechanisms of shear Alfven wave excitation and present a simple analytical formula giving the ratio of the coupled powers. Finally, we discuss the interpretation of some experimental results. DOE

SCATTERING BY A SMALL OBJECT CLOSE TO AN INTERFACE. 3. BURIED OBJECT

M. E. Ermutlu, K. Muinonen, K. A. Lumme, I. V. Lindell, and A. H. Sihvola Oct. 1994 20 p See also PB90-249806 and PB90-249814
(PB95-184909; ISBN-951-22-2297-3) Avail: CASI HC A03/MF A01

Exact Image Theory (EIT) is applied to the problem of electromagnetic wave scattering from a small object below the interface separating two isotropic and homogeneous media. The object is assumed to be electrically small so that it can be approximated by an electric dipole with known dyadic polarizability. Scattering from a buried small dielectric sphere is considered as an example of the theory. The present work might help us to understand light scattering by solar system dust particles in planetary regoliths, for which the so-called opposition effect and negative linear polarization have been observed; that is, nonlinear brightening and reversal of linear polarization near the backscattering direction. FAULT TOLERANT FEATURES AND EXPERIMENTS OF ANTS DISTRIBUTED REAL-TIME SYSTEM Semiannual Report, 16 Jul. 1994 - 15 Jan. 1995

Patrick Dominic-Savio, Jien-Chung Lo, and Donald W. Tufts 15 Jan. 1995 41 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0479)
(AD-A290133) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The ANTS project at the University of Rhode Island introduces the concept of Active Nodal Task Seeking (ANTS) as a way to efficiently design and implement dependable, high-performance, distributed computing. This paper presents the fault tolerant design features that have been incorporated in the ANTS experimental system implementation. The results of performance evaluations and fault injection experiments are reported. The fault-tolerant version of ANTS categorizes all computing nodes into three groups. They are: the up-and-running green group, the self-diagnosing yellow group and the failed red group. Each available computing node will be placed in the yellow group periodically for a routine diagnosis. In addition, for long-life missions, ANTS uses a monitoring scheme to identify faulty computing nodes. In this monitoring scheme, the communication pattern of each computing node is monitored by two other nodes. DTIC

INTERNAL ELECTRIC FIELD OF ANISOTROPIC AND BI-ANISOTROPIC SPHERES
A. Cherepanov and A. Sihvola Nov. 1994 17 p
(PB95-195491; ISBN-951-22-2371-6) Avail: CASI HC A03/MF A01

This paper discusses the problem of a spherical anisotropic scatterer exposed to a homogeneous electrostatic field. It has been common in the literature to treat this problem analogously to the case of an isotropic sphere for which it is known that the internal field is constant. In this paper, a proof is given for the uniformity of the field inside the anisotropic sphere, which--to the authors' knowledge--has not been proven before. This result puts those analyses on solid foundation in which the polarizability matrices of anisotropic inclusions are determined and the effective material parameters of anisotropic mixtures are calculated. In the present article, the proof is also generalized for bi-anisotropic spheres within an electromagnetostatic field. NTIS

DENOISING AND ROBUST NON-LINEAR WAVELET ANALYSIS
Andrew G. Bruce, David L. Donoho, Hong-Ye Gao, and R. D. Martin Apr. 1994 12 p Prepared in cooperation with Standford University, Stanford, CA Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A291668) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In a series of papers, Donoho and Johnstone develop a powerful theory based on wavelets for extracting non-smooth signals from noisy data. Several nonlinear smoothing algorithms are presented which provide high performance for removing Gaussian noise from a wide range of spatially inhomogeneous signals. However, like other methods based on the linear wavelet transform, these algorithms are very sensitive to certain types of non-Gaussian noise, such as outliers. In this paper, we develop outlier resistance wavelet transforms. In these transforms, outliers and outlier patches are localized to just a few scales: By using the outlier resistant wavelet transforms, we improve upon the Donoho and Johnstone nonlinear signal extraction methods. The outlier resistant wavelet algorithms are included with the S+Wavelets object-oriented toolkit for wavelet analysis. DTIC

This is a collaborative project between the - University of Oklahoma (OU) and Boston University (BU) studying the possibility of producing an infrared detector which integrates the function of a spectrometer. The successful implementation of these ideas could lead to a smart infrared detector. The system we are studying as a prototype is the two-dimensional electron system (2DES) GaAs-AlGaAs modulation-doped heterostructure system patterned with very narrow gates. This leads to a transition to an one-dimensional electron system (1 DES). We expect this system to be particularly sensitive to infrared radiation just at the crossover from a 2DES to a IDES. DTIC

(AD-A291785; ARO-28483.28-EL) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Work was studied on power combining applications using coplanar waveguide (cpw)-fed slot antenna oscillators. In this work, a large amount of oscillators are combined together to result in a high power source. The problems encountered with such systems is the non-linear interaction in the coupled-oscillators. As a single oscillator, we use a slot-antenna with a single microwave transistor designed to oscillate at 20 GHz. We have successfully combined a 2x2 array of these slot-antenna oscillators at 20 GHz to generate a total radiated power of 70 mW with a dc-RF efficiency of 15%. The power combining efficiency was 100%. Since the antennas are placed on a dielectric lens and therefore result in a high-gain pattern, the effective radiated power is around 4.5w. This configuration does not suffer from substrate mode problems and therefore can be easily extended to 94 GHz power combining systems. DTIC

NUMERICAL AND THEORETICAL STUDIES OF ROUGH SURFACE SCATTERING Final Report, 1 Apr. 1992 - 30 Sep. 1994
Eric I. Thorsos 28 Dec. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-92-G-0102)
(AD-A291748; ARO-29404.1-GS) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The goal of this project was to improve our understanding of electromagnetic scattering from conducting rough surfaces when the roughness is small in comparison with the radiation wavelength. Research was conducted in two related areas for p-polarized scattering from conducting surfaces: the generation of surface waves, and the development of renormalized perturbation theory for scattering from perfectly conducting surfaces. To understand the excitation of surface waves better, a numerical method was developed for displaying the field near the surface; surface waves can then be shown explicitly. The method is based on integral equation solutions, and no fundamental approximations are required. The existence of surface waves for p-polarized scattering leads to difficulties in theoretical treatments of scattering from conductors. This work is specialized to the case of scattering from perfect conductors, for which the theoretical problems are most evident. A renormalized perturbation theory is implemented that is free from the deficiencies inherent in standard perturbation theory. The renormalized perturbation theory is extended beyond lowest order, and comparisons with exact integral equation results show that this approach yields predictions for the bistatic scattering cross section that are accurate over a broad range of surface parameters. BINARY SEGMENTATION OF SAR IMAGES BY THE ICM ALGORITHM [SEGMENTACAO BINARIA DE IMAGENS SAR PELO ALGORITMO ICM]

Alejandro C. Frery and Nelson D. A. Mascarenhas 1993 12 p In PORTUGUESE

(INPE-5464-PRE/1772) Avail: CASI HC A03/MF A01

We present a derivation and an implementation of the ICM (Iterated Conditional Modes) algorithm for the binary segmentation of Synthetic Aperture Radar (SAR) images contaminated by a signal dependent noise called 'speckle'. The ICM algorithm is based on the modelling of the 'a priori' distribution under the Markov Random Fields framework. The obtained results with real SAR images display a significant improvement with respect to the pixel-by-pixel maximum likelihood classification, at a reasonable computational cost, with the incorporation of the spatial context. SAR NOISE REDUCTION THROUGH THE UTILIZATION OF ROBUST FILTERS [REDUCAO DE RUIDO EM IMAGENS SAR PELO USO DE FILTROS ROBUSTOS]

A. C. Frery and S. J. S. Santanna 1993 14 p In PORTUGUESE Study presented at the Brazilian Symposium on Remote Sensing, 7, Curitiba, 10-14 May 1993

(INPE-5504-PRE/1787) Avail: CASI HC A03/MF A01

After briefly reviewing some classical filters for speckle removal, we derive and implement three filters with characteristics of robustness suitable for speckle noise reduction: one based on the median; one based on the inter-quartile range; and one based on the median al absolute deviation. Assuming that observations within a synthetic aperture radar image are outcomes of independent Rayleigh random variables, these filters exhibit a good performance from both the signal-to-noise reduction and from the edge preserving criteria. The problem of filtering in an image is posed as an estimation problem. Author

DATA ACQUISITION SOFTWARE FOR DREO'S NEAR-FIELD ANTENNA MEASUREMENT FACILITY

Claude J. Brochu and Gilbert A. Morin Dec. 1994 61 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289819; DREO-1253) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

HREO has built an antenna anechoic facility for microwave and millimetre-wave measurement. The facility includes a spherical near-field antenna measurement system that allows far-field measurement of small antennas and near-field measurement of larger antennas (up to one meter) within the chamber. This report describes the facility including the equipment, the instrumentation, and the DREO Antenna Measurement Acquisition (DAMAS) software that was developed. The purpose of DAMAS is to control the measurement and acquisition process in real-time, and to present the data to the operator. The major objectives of this software development project were the streamlining of the process so that an antenna could be accurately characterized in the minimum amount of time, and the improvement of the reliability of the software. LOW-ANGLE TRACKING IN THE PRESENCE OF DUCTING, COHERENT AND INCOHERENT MULTIPATH

Eloi Bosse, Ross M. Turner, and Denis Dion Nov. 1994 53 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289838; DREO-1240) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report presents results on recent improvements to the low-angle tracking algorithm based on the Refined Maximum Likelihood (RML) method. Specifically the report describes results obtained for three different models: (1) the RML model; (2) a model which accounts for radar fluctuation of the specular return; (3) a third model which accounts for the effect of ducting. The results indicate that the simple RML model produces better results than obtained by using a model that attempts to account for the incoherent fluctuation in the specular direction. In the case of ducting, under moderate sea state conditions, the parabolic approximation of the Helmholtz wave equation gives accurate tracking while a simple two-ray multipath model (Kerr) is used for standard propagation conditions. For very high sea states, phase monopulse with averaging over a number of estimates at different frequencies gives sufficient accuracy for most applications. DTIC

HIGH PERFORMANCE GROUND PENETRATING RADAR SURVEY OF TA-49/AREA 2 Final Report

R. F. Hoeberling and M. J. Rangel, III (Analysis Programming Processing Instrumentation, Santa Barbara, CA.) Sep. 1994 31 p

(Contract W-7405-eng-36)

(DE95-006856; LA-12821-MS) Avail: CASI HC A03/MF A01

The results of high performance ground penetrating radar study of Area 2 at Technical Area 49 are presented. The survey was commissioned as part of Los Alamos Laboratory's continuing Environmental Remediation program and was completed and analyzed before borehole studies in Area 2 were started. Based upon the ground penetrating radar results, the location of one of the planned boreholes was moved to assure the drilling area was as safe as possible. While earlier attempts to use commercial radar devices at this facility had not been successful, the radar and digital processing system developed at Los Alamos were able to significantly improve the buried physical detail of the site. METHOD AND APPARATUS FOR MAINTAINING LINEARITY AND FREQUENCY ACCURACY OF AN FM CHIRP WAVEFORM Patent

Roger I. Martinez, inventor (to Navy), Michael L. Sanders, inventor (to

Navy), and John H. Ashton, inventor (to Navy) 27 Dec. 1994 13 p Filed 4 Apr. 1994
(AD-D017398; US-Patent-5,376,938; US-Patent-Appl-SN-224611; US-Patent-Class-342-128) Avail: US Patent and Trademark Office

A homodyne radar apparatus and method for performing radar cross-section measurement by maintaining the linearity and compensating for frequency drift of an FM (frequency modulation) chirp waveform produced by a YIG (yttrium-indium-garnet) tuned oscillator. A digital computer uses a predetermined data look-up table of each YIG oscillator frequency characteristic in conjunction with a digital to analog converter to provide a compensating sweep signal to linearize the frequency output of the oscillator. The computer uses an analog to digital converter in conjunction with a reference circuit output to compare the actual YIG signal nulls resulting from the reference circuit to the nulls in a signal produced by a lab standard oscillator in the reference circuit to adjust start sample delay of the ADC (analog-to-digital converter) and to correct any frequency drift evidenced by the difference in the null of the signal. ELECTRICAL PERFORMANCE CHARACTERISATION OF SINGLE-SHOT SWITCHES IN HIGH SPEED, HIGH VOLTAGE AND HIGH CURRENT APPLICATIONS
Michael Podlesak Aug. 1994 48 p
(DSTO-RR-0010; AR-008-582) Copyright Avail: Issuing Activity (DSTO, Melbourne Victoria, Austrailia)

The electrical performance characteristics of single-shot closing switches for slapper detonator applications were measured via the discharge of a low impedance transmission line. The switch performance, characterized by its time-dependent resistance behavior, could not be assessed via the more conventional methods of measurement because of high bandwidth requirements at comparatively high levels of voltage and current. Hence, an alternative technique based on a transmission line discharge was devised in which the time-dependent resistance of the switch can be determined from the measured current waveform of the switch, the initial open circuit voltage and the transmission line parameters only. Under certain conditions a simple lossless transmission line formula is sufficient for the calculation of the switch resistance waveform. However, if the transmission line losses cannot be neglected, a correction can be readily implemented through numerical signal processing. The bandwidth of this technique is limited to the bandwidth of the switch current measurement only, which proved to be particularly useful for the measurement of switches for slapper detonator applications where inductive pick-up noise in the switch voltage waveform is large and where high voltage probes of sufficiently high bandwidth are not readily available. In this report, both numerically simulated and experimental examples are given, together with the method of calculation of switch resistance which takes into account practical transmission line losses. It was found that best results are obtained if the magnitude of the switch resistance is of a similar order as the characteristic impedance of the transmission line, or higher. Author

HIGH POWER, BROADBAND FOLDED WAVEGUIDE GYROTRON-TRAVELING-WAVE-AMPLIFIER Patent Application
Carter M. Armstrong, inventor (to Navy), Jin J. Choi, inventor (to Navy), and Achintya K. Ganguly, inventor (to Navy) 30 Jun. 1994 35 p Filed 30 June 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288847; US-Patent-Appl-SN-269278; Navy-Case-76320) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A folded waveguide gyrotron-traveling-wave-amplifier comprises: an electron gun for transmitting an axis-encircling beam of electrons with large transverse energy along a first path having an axis; an RF source for producing and applying in a second path an RF input millimeter wave signal having a bandwidth in a preselected frequency domain and having a transverse electric field; a source for generating a solenoid magnetic field parallel to the axis along the first path; a beam collector; and an interaction circuit such as an H-plane bend serpentine waveguide positioned within the solenoid magnetic field and having a narrow wall containing a beam tunnel hole for passing the axis-encircling beam of electrons there through to the beam collector, an output end, and an input end for receiving and passing the RF input millimeter wave signal through the H-plane bend serpentine waveguide to the output end to modulate the axis-encircling electron beam, the modulated axis-encircling electron beam amplifying the RF input signal and also broadening the instantaneous bandwidth of the amplified RF input signal through the negative mass instability in the fundamental forward space harmonic of both fast and slow wave regions in the preselected frequency domain. In a second embodiment, a double-ridged TE folded waveguide is used in place of the H-plane bend serpentine waveguide. In a third embodiment, there is no RF input signal and the interaction circuit generates an RF signal which is outputted from one of the input and output ends. DTIC

MICROWAVE CIRCUIT SIMULATION USING HIGHER-ORDER DYNAMIC ELEMENTS
Martti Valtonen Oct. 1994 41 p
(ISSN 0784-5979)
(PB95-185088; ISBN-951-22-2301-5) Avail: CASI HC A03/MF A01

Realizations of a memristor, R-, L-, C-, and M-dynamic elements, as well as mixed and higher-order dynamic elements, are given with the aid of static and dynamic voltage-controlled current sources. The dynamic elements are treated with several state variables and ports. The memristor as well as R-, L-, C-, and M-dynamic elements with arbitrary number of state variables, are implemented in circuit design tool APLAC. As an application, a circuit model for the MESFET trapping and abrupt doping effects is presented that describes the small-signal output conductance and susceptance of a sample MESFET as a function of frequency and drain voltage in the range of f = 20 Hz,..., 1 MHz and V(D) = 0.5 V,..., 3 V. The model simulates the measured properties of the sample MESFET in a qualitative manner. NTIS

INTELLIGENT COMPUTER BASED RELIABILITY ASSESSMENT OF MULTICHIP MODULES Final Technical Report, 7 Apr. 1993 - 6 Apr. 1994
Ian R. Grosse, Prasanna Katragadda, Sandeepan Bhattacharya, and Sarang

Kulkarni 6 Apr. 1994 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F30602-93-C-0084)
(AD-A288833) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

To deliver reliable Multichip (MCM's) in the face of rapidly changing technology, computer-based tools are needed for predicting the thermal mechanical behavior of various MCM package designs and selecting the most promising design in terms of performance, robustness, and reliability. The design tool must be able to address new design technologies manufacturing processes, novel materials, application criteria, and thermal environmental conditions. Reliability is one of the most important factors for determining design quality and hence must be a central condition in the design of Multichip Module packages. Clearly, design engineers need computer based simulation tools for rapid and efficient electrical, thermal, and mechanical modeling and optimization of advanced devices. For three dimensional thermal and mechanical simulation of advanced devices, the finite element method (FEM) is increasingly becoming the numerical method of choice. FEM is a versatile and sophisticated numerical techniques for solving the partial differential equations that describe the physical behavior of complex designs. AUTOTHERM(TM) is a MCM design tool developed by Mentor Graphics for Motorola, Inc. This tool performs thermal analysis of MCM packages using finite element analysis techniques. The tools used the philosophy of object oriented representation of components and simplified specification of boundary conditions for the thermal analysis so that the user need not be an expert in using finite element techniques. Different package types can be assessed and environmental conditions can be modeled. It also includes a detailed reliability module which allows the user to choose a desired failure mechanism (model). All the current tools perform thermal and/or stress analysis and do not address the issues of robustness and optimality of the MCM designs and the reliability prediction techniques are based on closed form analytical models and can often fail to predict the cycles of failure (N(f)) by order of magnitude, although they can be used to compare the different designs. Candidate MCM designs are evaluated in terms of the reliability performance parameters (maximum temperature/stress/strain) rather than the absolute reliability of the device. In this regard we propose a methodology and associated computer based design tool for multichip modules which embodies these ideas and addresses the issues of optimum and robust MCM package design. An object oriented approach and design of experiments methodology is adopted and integrated into the already existing Intelligent Multichip Module Analyzer (IMCMA) system. Derived from text

SURVEY ON STEP RECOVERY DIODE AND ITS APPLICATIONS
Zhang Jian and Antti Raeisaenen Sep. 1994 30 p
(ISSN 1237-4938)
(PB95-184974; S-208; ISBN-951-22-2270-1) Avail: CASI HC A03/MF A01

The state of the art of the step recovery diode (SRD) and its applications are reviewed from the very beginning up to now. Used as a charge controlled switch, the SRD has found extensive applications in frequency comb generation, frequency multiplication, and pulse shaping and waveform generating circuits. The designs of SRD circuits are based on the idealized nonlinear capacitance model of the SRD. The frequency-domain analyses of SRD circuits have been developed and the circuits simulated with computers. With the development of the SRD device itself, the SRD has the great prospect of being used at millimeter and even at submillimeter wavelengths. More accurate analyses and designs should, therefore, be studied correspondingly. A list of the publications concerning the SRD is furnished at the end of this report. NTIS

AN OPTOELECTRONIC ATTENUATOR FOR THE HIGH-SPEED CONTROL OF MICROWAVE INTEGRATED CIRCUITS Final Report, Nov. 1990 - Dec. 1993
Stephen E. Saddow and Chi H. Lee Nov. 1994 83 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289579; ARL-TR-387) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An optoelectronic attenuator suitable for the optical control of microwave integrated circuits is presented. High-speed photoconductive switches are embedded in planar microwave transmission lines, and semiconductor laser diodes (LD's) are used to control the microwave signal level on these high-speed lines. With a silicon coplanar waveguide-photoconductive switch (Si:CPW-PCS), up to 45 dB of microwave attenuation has been achieved with a fiber-pigtailed laser diode having 144 mW of optical power. Measurements made using a vector network analyzer show that the attenuator performance can be explained by a classical plasma absorption argument, whereby the microwave signal is attenuated by the optically induced solid-state plasma. Edge-coupled Fabry-Perot aluminum-gallium-arsenide/gallium-arsenide (AlGaAs/GaAs) semiconductor LD's, as well as both silicon and gallium-arsenide (GaAs) CPW-PCS's, were developed for the optoelectronic attenuator. When conventional gain-switching techniques are used, LD peak output powers greater than 1 W have been demonstrated, and when an optical Q-switching scheme is used, 6 W of peak power has been achieved in tens of picoseconds. Silicon based microelectromechanical (MEM) devices using both surface and bulk micromachining have been realized to provide tactile stimulation. The bulk MEM devices utilize the bimorph principle and are fabricated in a complementary metal oxide semiconductor (CMOS) process through MOS implementation system (MOSIS). The surface MEM devices utilize the electrostatic principle and are fabricated in the multi-user MEM process (MUMPS) through MCNC. Eleven major designs are presented and tested to determine if they are suitable to provide tactile stimulation. The bimorph and electrostatic designs were tested using a probe station, a laser interferometer, and a force tester. Measurements were taken on the deflections, cutoff frequencies, and loaded operation of the devices. The bimorph designs fabricated in the CMOS process showed the most potential. The tests results indicate that the cantilever beam designs deflect over 30 microns. They operate at frequencies below 130 Hz. The devices operate under a load of approximately 5 microN. An endurance test was performed by actuating a device over 2.5 million times. DTIC

MATERIALS, STRUCTURES, AND DEVICES FOR HIGH-SPEED ELECTRONICS Final Report, 1 Jan. 1981 - 31 Dec. 1992
John A. Woollam and Paul G. Snyder 31 Dec. 1992 29 p
(Grant NAG3-154)
(NASA-CR-197815; NAS 1.26:197815) Avail: CASI HC A03/MF A01

Advances in materials, devices, and instrumentation made under this grant began with ex-situ null ellipsometric measurements of simple dielectric films on bulk substrates. Today highly automated and rapid spectroscopic ellipsometers are used for ex-situ characterization of very complex multilayer epitaxial structures. Even more impressive is the in-situ capability, not only for characterization but also for the actual control of the growth and etching of epitaxial layers. Spectroscopic ellipsometry has expanded from the research lab to become an integral part of the production of materials and structures for state of the art high speed devices. Along the way, it has contributed much to our understanding of the growth characteristics and material properties. The following areas of research are summarized: Si3N4 on GaAs, null ellipsometry; diamondlike carbon films; variable angle spectroscopic ellipsometry (VASE) development; GaAs-AlGaAs heterostructures; Ta-Cu diffusion barrier films on GaAs; GaAs-AlGaAs superlattices and multiple quantum wells; superconductivity; in situ elevated temperature measurements of III-V's; optical constants of thermodynamically stable InGaAs; doping dependence of optical constants of GaAs; in situ ellipsometric studies of III-V epitaxial growth; photothermal spectroscopy; microellipsometry; and Si passivation and Si/SiGe strained-layer superlattices. The invention disclosed in this document is a brushless DC motor including a housing having an end cap secured thereto. The housing encloses a rotor, a stator and a rotationally displaceable commutation board having 5 sensors secured thereon and spaced around the periphery of the rotor. An external rotational force is applied to the commutation board for displacement of the sensors to various positions whereby varying feedback signals are generated by the positioning of the sensors relative to the rotating rotor. The commutation board is secured in a fixed position in response to feedback signals indicative of optimum sensor position being determined. The rotation of the commutation board and the securing of the sensors in the desired fixed position is accomplished without requiring the removal of the 5 end cap and with the DC motor operating. DESIGN AND CHARACTERIZATION OF RESONANT CAVITY LIGHT-EMITTING DIODES M.S. Thesis
Thomas M. Fitzgerald Dec. 1994 135 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289307; AFIT/GEO/ENP/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis describes an investigation into the emission properties of Resonant Cavity Light Emitting Diodes (RCLED). RCLED's are a new photonic device that promise laser-like properties of narrow output frequency spread and high output power, without the usual laser disadvantages of shorter lifetime and increased maintenance and lifetime costs. Specifically, this thesis examines the functional dependence between emitted wavelength and the RCLED microcavity, and attempts to correlate theory with experimental data. This thesis introduces a classical wave interference model that calculates the Spontaneous Emission Enhancement Factor (Z-) with angular dependence. DTIC

(Contract N00014-93-1-0231)
(AD-A289238) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Anticausal inversion of IIR transfer functions has gained importance in recent years, in the efficient implementation of IIR digital filter banks. In this paper we first introduce the idea of a causal dual, as an intermediate step in the implementation of anticausal IIR inverses. With time reversal operators at the input and output of the causal dual, we get the anticausal inverse of the original structure. The causal dual eliminates the need for similarity transformations, during a key step called blockwise state transfer, in implementing anticausal inverses. In the paper we identify efficient structures for causal duals of standard structures like the direct-form, cascade-form, coupled form, and IIR lattice structures, including the tapped lattice. DTIC

(Contract N00014-92-J-1190)
(AD-A289181; ECE/GWOL/62) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Optical injection of MESFET's directly affects the operating characteristics of the devices. The MESFET properties, induced by optical injection, can stabilize oscillator operating frequency, control amplifier gain, and open the door for feasible integrated microwave-optical devices. The optical injection of DC MESFET's, oscillators, and amplifiers is explored. Systems applications, including phased array radar, wave division multiplexing (WDM), and computer clock control, are provided. The main contributions of this research are analyzing the modulation properties of the locked laser subsystem, using the locked laser system to inject MESFET devices and characterizing the photo-effects in MESFET circuits, reducing the phase noise in a microwave oscillator via optical injection, and developing a theoretical description of the injection properties of oscillators that can be used to describe an injection locked laser and a microwave oscillator with a change of constants. COMPARISON OF THE RESISTANCE OF THE MOS INTEGRATED CIRCUITS WITH VARIOUS TYPES OF NUCLEAR RADIATION
A. Yu. Didyk, G. G. Gulbekyan, and W. Wronski 1994 10 p
(DE95-608623; JINR-E-14-94-217) Avail: CASI HC A02/MF A01 (US Sales Only)

Principal conceptions on simulation of radiation effects in semiconductor devices caused by fast neutrons with the use of accelerated heavy ions with the energies exceeding 1 MeV/n are presented. Models explaining radiation effects on semiconductors and devices thereof under radiation ionization are described. Experimental results on parameter degradation of shift registers at irradiation by heavy ions, electrons, gamma-quanta, and fast neutrons are obtained. On the basis of data obtained the efficiency coefficients and terminal threshold fluences for different types of radiation ionization are determined. DOE

INVESTIGATION OF RADIATION RESISTANCE OF TRANSISTORS AND INTEGRATED CIRCUITS USING THE HEAVY IONS BEAM OF ENERGY HIGHER THAN 1 MeV/amu AND FAST NEUTRONS
A. Yu. Didyk, V. N. Nazarov, G. G. Gulbekyan, and W. Wronski 1994 11 p
(DE95-608624; JINR-E-14-94-218) Avail: CASI HC A03/MF A01 (US Sales Only)

Planar transistors and logical gates NAND were irradiated at ion beam of Ne-22 and C-12 of the energy 27.9 MeV and 91 MeV, respectively. The degradation of the direct current gain (h(sub 21E)) and the output voltage of the logical level '1' have been recorded. The exposition dose limits (EDL), which are measure of the radiation resistance of the investigated devices for ions as well as for fast neutrons, have been determined. On the basis of the EDL values the efficiency coefficients of the heavy ions in relation to fast neutrons have also been determined. DOE

TESTING OF UNINTERRUPTIBLE POWER SUPPLIES WITH NONLINEAR LOADS Final Report

Gerald Heydt, Steve Briggs, Franklin Holcomb, and Daiva Edgar Sep. 1994 88 p Prepared in cooperation with Purdue University Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DA Proj. 4A1-62784-AT-45)
(AD-A289353; CERL-FE-94/23) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Uninterruptible power supplies (UPS's) are used to provide power to sensitive and critical loads when the commercial supply has been interrupted. These loads may be nonlinear, which in the military often includes communications equipment, adjustable speed drives, fluorescent lighting, and mainframe and small computers. Most electrical characteristics of UPS's are not currently subject to codes and standards, and there are no military specifications for UPS's. Existing standards assume that UPS's will be operated with linear loads. Since most UPS systems are operated with nonlinear loads, there is concern that UPSs will suffer degraded performance or failure when operated with these loads. This work developed a test methodology by which UPS systems can be tested and their susceptibility to nonlinear loads quantified. The tests measure load transfer, efficiency, heating, load support, voltage regulation, and isolation. Several commercially available UPS systems are recommended for testing. DTIC

NOVEL FIELD EFFECT TRANSISTORS FOR LOW POWER ELECTRONICS Progress Report No. 2

28 Nov. 1994 9 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-C-0260)
(AD-A288650) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The primary objective of this Phase 1 project is to determine the extent of the significant reduction in power consumption of integrated circuits which may be achieved by utilizing a novel sidegate FET technology. The new FET technology promises to eliminate the Narrow Channel Effect (NCE) which is one of the primary factors limiting the minimum power consumption of integrated circuits. By eliminating the NCE, we will be able to scale the device size dramatically and reduce the power consumption by an order of magnitude. The project will assess the power, speed, circuit design, processing, and manufacturability of the new FET technology for both digital and analog circuit applications. In particular, we will extract device parameters from the new ultra-low power FETs fabricated at UVa, develop device models, incorporate these models into a new SPICE package (AIM-Spice), simulate different logic families including DCFL and SCFL, and compare the predicted performance with the standard DCFL and SCFL logic. We will also analyze the gate current leakage and subthreshold slope as the primary factors limiting the noise margins at low power supplies, establish the minimum required bias voltage for reliable operation, and analyze the factors determining the threshold voltage changes from device to device as well as other factors which may limit the yield and integration scale. DTIC

A FINITE ELEMENT BASED TECHNIQUE FOR SIMULATION HELIX TWT INTERACTION CIRCUIT THERMAL BEHAVIOR Report, Jan. 1993 - Apr. 1994

Peter J. Rocci Oct. 1994 30 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2338)
(AD-A289552; RL-TR-94-166) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A technique was developed to assess the thermal performance of a helix Traveling Wave Tube (TWT) interaction circuit accounting for the thermal contact resistance between the circuit's components. This method employed iterative finite element analyses techniques and an analytical expression that related contact pressure to thermal contact resistance. Temperature gradients across the interfaces between the helix and support rods and between the support rods and barrel increase operating temperatures, which can lead to a decline in the tube's performance. Since the circuit analyzed contained no brazes or epoxy at the component interfaces, these thermal drops become more significant. parametric runs were made using this methodology for different assembly loads as well as for both beryllia and boron nitride (APBN) support rods. Results showed that the thermal contact resistance effect was more pronounced at lower assembly loads and higher thermal loads. That is, as the thermal loading to the circuit increases, the percent increase of the maximum helix temperature over the helix temperature when the resistance is not accounted for, increases. This effect was also more pronounced when APBN support rods were modeled. The helix temperature increased a greater amount when accounting for the thermal contact resistance for APBN support rods than for BeO support rods. DTIC

(Grant NSF ENG-92-17849)
(NASA-CR-197830; NAS 1.26:197830; PB95-188116; ISBN-1-88712-37-8)
Avail: CASI HC A12/MF A03

This report summarizes the status of electronic manufacturing and packaging technology in Japan in comparison to that in the United States, and its impact on competition in electronic manufacturing in general. In addition to electronic manufacturing technologies, the report covers technology and manufacturing infrastructure, electronics manufacturing and assembly, quality assurance and reliability in the Japanese electronics industry, and successful product realization strategies. The panel found that Japan leads the United States in almost every electronics packaging technology. Japan clearly has achieved a strategic advantage in electronics production and process technologies. Panel members believe that Japanese competitors could be leading U.S. firms by as much as a decade in some electronics process technologies. For individual titles, see N95-27227 through N95-27233.

MICROELECTRONICS IN JAPAN
William R. Boulton (Auburn Univ., AL.) *In its* JTEC Panel Report on Electronic Manufacturing and Packaging in Japan Feb. 1995 p 1-20 (For primary document see N95-27226 09-33)
Avail: CASI HC A03/MF A03

The purpose of this JTEC study is to evaluate Japan's electronic manufacturing and packaging capabilities within the context of global economic competition. To carry out this study, the JTEC panel evaluated the framework of the Japanese consumer electronics industry and various technological and organizational factors that are likely to determine who will win and lose in the marketplace. This study begins with a brief overview of the electronics industry, especially as it operates in Japan today. Succeeding chapters examine the electronics infrastructure in Japan and take an in-depth look at the central issues of product development in order to identify those parameters that will determine future directions for electronic packaging technologies. BUILDING THE ELECTRONIC INDUSTRY'S ROADMAPS
William R. Boulton (Auburn Univ., AL.) *In its* JTEC Panel Report on Electronic Manufacturing and Packaging in Japan Feb. 1995 p 21-34 (For primary document see N95-27226 09-33)
Avail: CASI HC A03/MF A03

JTEC panelists found a strong consistency among the electronics firms they visited: all the firms had clear visions or roadmaps for their research and development activities and had committed resources to ensure that they achieve targeted results. The overarching vision driving Japan's electronics industry is that of achieving market success through developing appealing, high-quality, low-cost consumer goods - ahead of the competition. Specifics of the vision include improving performance, quality, and portability of consumer electronics products. Such visions help Japanese companies define in detail the roadmaps they will follow to develop new and improved electronic packaging technologies. Author

JAPAN'S ELECTRONIC PACKAGING TECHNOLOGIES
Rao R. Tummala (Georgia Inst. of Tech., Atlanta, GA.) and Michael Pecht (Maryland Univ., College Park, MD.) *In its* JTEC Panel Report on Electronic Manufacturing and Packaging in Japan Feb. 1995 p 59-96 (For primary document see N95-27226 09-33)
Avail: CASI HC A03/MF A03

The JTEC panel found Japan to have significant leadership over the United States in the strategic area of electronic packaging. Many technologies and products once considered the 'heart and soul' of U.S. industry have been lost over the past decades to Japan and other Asian countries. The loss of consumer electronics technologies and products is the most notable of these losses, because electronics is the United States' largest employment sector and is critical for growth businesses in consumer products, computers, automobiles, aerospace, and telecommunications. In the past there was a distinction between consumer and industrial product technologies. While Japan concentrated on the consumer market, the United States dominated the industrial sector. No such distinction is anticipated in the future; the consumer-oriented technologies Japan has dominated are expected to characterize both domains. The future of U.S. competitiveness will, therefore, depend on the ability of the United States to rebuild its technological capabilities in the area of portable electronic packaging. Author

ELECTRONICS MANUFACTURING AND ASSEMBLY IN JAPAN
John A. Kukowski (Rochester Inst. of Tech., NY.) and William R. Boulton (Auburn Univ., AL.) *In its* JTEC Panel Report on Electronic Manufacturing and Packaging in Japan Feb. 1995 p 97-114 (For primary document see N95-27226 09-33)
Avail: CASI HC A03/MF A03

In the consumer electronics industry, precision processing technology is the basis for enhancing product functions and for minimizing components and end products. Throughout Japan, manufacturing technology is seen as critical to the production and assembly of advanced products. While its population has increased less than 30 percent over twenty-five years, Japan's gross national product has increase thirtyfold; this growth has resulted in large part from rapid replacement of manual operations with innovative, high-speed, large-scale, continuously running, complex machines that process a growing number of miniaturized components. The JTEC panel found that introduction of next-generation electronics products in Japan goes hand-in-hand with introduction of new and improved production equipment. In the panel's judgment, Japan's advanced process technologies and equipment development and its highly automated factories are crucial elements of its domination of the consumer electronics marketplace - and Japan's expertise in manufacturing consumer electronics products gives it potentially unapproachable process expertise in all electronics markets. QUALITY ASSURANCE AND RELIABILITY IN THE JAPANESE ELECTRONICS INDUSTRY
Michael Pecht (Maryland Univ., College Park, MD.) and William R. Boulton (Auburn Univ., AL.) *In its* JTEC Panel Report on Electronic Manufacturing and Packaging in Japan Feb. 1995 p 115-126 (For primary document see N95-27226 09-33)
Avail: CASI HC A03/MF A03

Quality and reliability are two attributes required for all Japanese products, although the JTEC panel found these attributes to be secondary to customer cost requirements. While our Japanese hosts gave presentations on the challenges of technology, cost, and miniaturization, quality and reliability were infrequently the focus of our discussions. Quality and reliability were assumed to be sufficient to meet customer needs. Fujitsu's slogan, 'quality built-in, with cost and performance as prime consideration,' illustrates this point. Sony's definition of a next-generation product is 'one that is going to be half the size and half the price at the same performance of the existing one'. Quality and reliability are so integral to Japan's electronics industry that they need no new emphasis. Author

SUCCESSFUL PRODUCT REALIZATION STRATEGIES
John Peeples (American Telephone and Telegraph Co., West Columbia, SC.) and William R. Boulton (Auburn Univ., AL.) *In its* JTEC Panel Report on Electronic Manufacturing and Packaging in Japan Feb. 1995 p 127-154 (For primary document see N95-27226 09-33)
Avail: CASI HC A03/MF A03

Product realization is the process of defining, designing, developing, and delivering products to the market. While the main thrust of this JTEC panel was to conduct a complete investigation of the state of Japanese low-cost electronic packaging technologies, it is very difficult to totally separate the development of technology and products from the product realization process. Japan's electronics firms adhere to a product realization strategy based on a strong customer focus, a consistent commitment to excellence in design, and a cost-effective approach to technology commercialization. The Japanese product-pull strategy has been a successful driver and influencing factor in every aspect of the product development cycle. Author

ACCELERATING CONSERVATIVE PARALLEL SIMULATION OF VHDL CIRCUITS M.S. Thesis
Joel F. Hurford Dec. 1994 96 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289317; AFIT/GCS/ENG/94D-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research effort considers heuristic and cost model based techniques for the optimal partitioning of VHDL circuits for parallel simulation. Correlation statistics are gathered on a wide variety of graph-based a priori parameters. Linear regression is used to identify significant parameters for inclusion in a representative cost model. Driving a greedy search, this cost model is used to improve upon initial heuristic partitions. The influence of feedback dominated previous research so a no-feedback algorithm is used to create the initial partition. The circuits studied range from 1050 to 4243 gates. DTIC

MODEL OF A SINGLE IMPURITY IN A WIDE BANDGAP SEMICONDUCTOR DESCRIBING ELECTRIC FIELD SCREENING M.S. Thesis
Anthony N. Dills Dec. 1994 77 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289322; AFIT/GAP/ENP/94D-3) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A mathematical model of the influence on electric field screening arising from a single impurity in a wide bandgap semiconductor has been numerically investigated and compared with analytically derived solutions. The parameter set chosen to perform the comparison of analytical solution and numerical solution is based upon a bismuth silicate crystal. Both the analytical calculations and the numerical calculations are an attempt to mathematically model the internal electric field within a semiconductor. Two types of impurities were looked at: a single donor level and a single trap impurity level. In general, after an abrupt application of a voltage across the semiconductor, net charge regions begin to redistribute and create internal electric fields that screen the applied field. A trap impurity is found to be more self-consistent with the analytical solutions than a donor impurity, the former satisfying the assumption of a constant free electron lifetime. The analytical solutions are valid for observation times much less than the Maxwellian relaxation time tau sub M: t much less than tau sub M. The analytical solution properly predicts stratification conditions when the observation time is prior to tau sub M; however, oscillatory behavior, characteristic of stratification, of the internal electric field occurs for times much greater than tau sub M. During this regime the analytical solutions are invalid. DTIC

THE 77 K OPERATION OF A MULTI-RESONANT POWER CONVERTER
Biswajit Ray (National Academy of Sciences - National Research Council, Cleveland, OH.), Scott S. Gerber (NYMA, Inc., Brook Park, OH.), Richard L. Patterson, and Ira T. Myers May 1995 8 p Presented at the Power Engineering Society Conference, Atlanta, GA, 18-22 Jun. 1995; sponsored by IEEE
(Contract NAS3-27186; RTOP 233-02-0C)
(NASA-TM-106941; E-9669; NAS 1.15:106941) Avail: CASI HC A02/MF A01

The liquid-nitrogen temperature (77 K) operation of a 55 W, 200 kHz, 48/28 V zero-voltage switching multi-resonant dc/dc converter designed with commercially available components is reported. Upon dipping the complete converter (power and control circuits) into liquid-nitrogen, the converter performance improved as compared to the room-temperature operation. The switching frequency, resonant frequency, and the characteristic impedance did not change significantly. Accordingly, the zero-voltage switching was maintained from no-load to full-load for the specified line variations. Cryoelectronics can provide high density power converters, especially for high power applications. Author

ELECTROMAGNETIC HYSTERETIC RESPONSE CALCULATION FOR SUPERCONDUCTORS IN DEMAGNETIZING GEOMETRIES
L. S. Koo and K. L. Telschow 1994 6 p Presented at the 1994 Review of Progress in Quantitative Nondestructive Evaluation Conference, Snowmass, CO, 31 Jul. - 5 Aug. 1994
(Contract DE-AC07-76ID-01570)
(DE95-005028; EGG-M-94113; CONF-9407123-5) Avail: CASI HC A02/MF A01

A method has been outlined for calculating the flux front profile for a superconducting sample in either a uniform or nonuniform applied magnetic field possessing azimuthal symmetry. This technique relies upon finding a surface with zero vector potential. This surface is determined by simple integration of its derivative with respect to the external field, found by resolving a linear integral equation of the first kind. Measurement induced voltages and the entire hysteresis loop response can be found by extension of the ZFC magnetization response with increasing external field. Other experimentally measured quantities relating to the critical state can be calculated directly from the hysteresis loop if the time dependence of the external field is known. The technique shown in this report for solving the critical state model in the Bean approximation can be extended to field-dependent critical currents and other azimuthally symmetrical external fields. This work is presently in progress. DOE

THE EFFECTS OF TEMPERATURE ON SCHOTTKY DIODE BARRIER HEIGHT AND EVIDENCE OF MULTIPLE BARRIER
K. V. O. Rabah Jul. 1994 27 p
(DE95-609147; IC-94/181) Avail: CASI HC A03/MF A01 (US Sales Only)

Experimental study of Capacitance-Voltage-Temperature (C-V-T) plots, Current-Voltage-Temperature (I-V-T) characteristics have been undertaken in order to determine the height of the Schottky barrier. The results of the barrier height obtained by the above two methods were found to differ as well as vary with temperature change. In view of this discrepancy in barrier height values, two further experiments were performed: one on activation energy (I-T) plots and the other on pulsed (I-V-T) characteristics, and the results were found to show a similar trend. The Schottky diode studied was a 30CP040. DOE

ELECTROLYTE EFFECTS IN LI(SI)/FeS2 THERMAL BATTERIES
Ronald A. Guidotti and Frederick W. Reinhardt 1994 17 p Presented

at the 19th International Power Sources Symposium, Brighton, England, 24-26 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-001614; SAND-94-1870C; CONF-950461-1) Avail: CASI HC A03/MF A01

The most common electrochemical couple for thermally activated ('thermal') batteries is the Li-alloy/FeS2 system. The most common Li-alloys used for anodes are 20% Li-80% Al and 44% Li-56% Si (by weight); liquid Li immobilized with iron powder has also been used. The standard electrolyte that has been used in thermal batteries over the years is the LiCl-KCl eutectic that melts at 352 C. The LiCl-LiBr-LiF eutectic had the best rate and power characteristics. This electrolyte melts at 436(degrees)C and shows very low polarization because of the absence of Li(+) gradients common with the LiCl-KCl eutectic. The low-melting electrolytes examined included a KBr-LiBr-LiCl eutectic (melting at 321 C), a LiBr-KBr-LiF eutectic (melting at 313 C), and a CsBr-LiBr-KBr eutectic (melting at 238 C). The CsBr-based salt had poor conductivity and was not studied further. The LiBr-KBr-LiF eutectic outperformed the KBr-LiBr-LiCl eutectic and was selected for more extensive testing. Because of their lower melting points and larger liquidi relative to the LiCl-KCl eutectic, the low-melting electrolytes are prime candidates for long-life applications (i.e., for activated lives of one hour or more). This paper will detail the relative performance of the Li(Si)/FeS2 couple using primarily the LiCl-KCl (standard) eutectic, the LiCl-LiBr-LiF (all-Li) eutectic, and the LiBr-KBr-LiF (low-melting) eutectic electrolytes. Most of the tests were conducted with 5-cell batteries; validation tests were also carried out with appropriate full-sized batteries. DOE

INDUCED AXIAL OSCILLATIONS IN SUPERCONDUCTING DIPOLE WINDINGS
W. B. Sampson and A. K. Ghosh 1994 4 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract DE-AC02-76CH-00016)
(DE95-005690; BNL-60349; CONF-941013-23) Avail: CASI HC A01/MF A01

When superconducting accelerator magnets wound from multi-stranded conductor are energized a periodic variation appears in the magnetic field along the axis. This oscillation is present in al components of the field and has a period that is equal to the transposition pitch of the superconducting cable. Such axial variations have been observed even in windings which are not carrying any transport current. A magnetic field was applied to a portion of a dipole winding using a second magnet. Axial oscillations were induced along the total length of the windings including the portion not in the applied field. The amplitude of these oscillations varied with the amount of inert winding inside the energizing magnet and with t;he angle of the applied field. These field variations could be completely applied field. These field variations could be completely eliminated in the external portion of the coil by heating a small section of the winding above the transition temperature. DOE

AMORPHOUS SILICON PIXEL RADIATION DETECTORS AND ASSOCIATED THIN FILM TRANSISTOR ELECTRONICS READOUT
V. Perez-Mendez, J. Drewery, W. S. Hong, T. Jing, S. N. Kaplan, H. Lee, and A. Mireshghi Oct. 1994 21 p Presented at the Electrochemical Society Thin Film Technology Symposium, Miami, FL, 10-14 Oct. 1994
(Contract DE-AC03-76SF-00098)
(DE95-006568; LBL-36025; CONF-941063-12) Avail: CASI HC A03/MF A01

We describe the characteristics of thin (1 micrometer) and thick (greater than 30 micrometers) hydrogenated amorphous silicon p-i-n diodes which are optimized for detecting and recording the spatial distribution of charged particles, x rays and (gamma) rays. For x ray, (gamma) ray, and charged particle detection we can use thin p-i-n photosensitive diode arrays coupled to evaporated layers of suitable scintillators. For direct detection of charged particles with high resistance to radiation damage, we use the thick p-i-n diode arrays. Deposition techniques using helium dilution, which produce samples with low stress are described. Pixel arrays for flux exposures can be readout by transistor, single diode or two diode switches. Polysilicon charge sensitive pixel amplifiers for single event detection are described. Various applications in nuclear, particle physics, x ray medical imaging, neutron crystallography, and radionuclide chromatography are discussed. DOE

COMPARISON OF THE CALCULATED AND MEASURED STABILITY OF A NbTi CABLE-IN-CONDUIT CONDUCTOR
R. L. Wong and C. T. Yeaw (Wisconsin Univ., Madison, WI.) 13 Oct. 1994 6 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract W-7405-eng-48)
(DE95-007964; UCRL-JC-116965; CONF-941013-26) Avail: CASI HC A02/MF A01

Calculated curves of cable-in-conduit conductor energy stability margins vs. current are compared to experimental curves obtained at Oak Ridge National Laboratory for NbTi single triplex conductors. The conductors ranged in length from 1.8 m to 4.8 m, and had no imposed helium flow. The initiating heat pulse was applied for 16.7 ms over the entire conductor length. The calculated stability curves display the large decrease in energy margin from the low current and high energy margin 'well-cooled' stability region, to the high current and low energy margin 'ill-cooled' region that was determined experimentally. The calculated 'limiting current' of 250 A (boundary between the ill-cooled and well-cooled regions) also agrees with experiment. The multi-valued stability margins measured for lengths of 3.1 and 3.8 m could not be obtained by the computer model. Excluding the multiple stabilities, the calculated margins are generally 30% lower than the experimental values. The decrease in energy margin in the ill-cooled region was found to be due to the low critical to operating temperature difference (2.2 K at 250 A). This prevents an initiating pulse in the ill-cooled region from being able to generate significant Joule heating without quenching, limiting the energy margin. DOE

CURRENT STATUS OF ENVIRONMENTAL, HEALTH, AND SAFETY ISSUES OF LITHIUM POLYMER ELECTRIC VEHICLE BATTERIES
D. Corbus and C. J. Hammel Feb. 1995 76 p
(Contract DE-AC36-83CH-10093)
(DE95-004005; NREL/TP-463-7540) Avail: CASI HC A05/MF A01

Lithium solid polymer electrolyte (SPE) batteries are being investigated by researchers worldwide as a possible energy source for future electric vehicles (EV's). One of the main reasons for interest in lithium SPE battery systems is the potential safety features they offer as compared to lithium battery systems using inorganic and organic liquid electrolytes. However, the development of lithium SPE batteries is still in its infancy, and the technology is not envisioned to be ready for commercialization for several years. Because the research and development (R&D) of lithium SPE battery technology is of a highly competitive nature, with many companies both in the United States and abroad pursuing R&D efforts, much of the information concerning specific developments of lithium SPE battery technology is proprietary. This report is based on information available only through the open literature (i.e., information available through library searches). Furthermore, whereas R&D activities for lithium SPE cells have focused on a number of different chemistries, for both electrodes and electrolytes, this report examines the general environmental, health, and safety (EH&S) issues common to many lithium SPE chemistries. However, EH&S issues for specific lithium SPE cell chemistries are discussed when sufficient information exists. Although lithium batteries that do not have a SPE are also being considered for EV applications, this report focuses only on those lithium battery technologies that utilize the SPE technology. The lithium SPE battery technologies considered in this report may contain metallic lithium or nonmetallic lithium compounds (e.g., lithium intercalated carbons) in the negative electrode. DOE

TIME-OPTIMAL CONTROL OF THE MAGNETICALLY LEVITATED PHOTOLITHOGRAPHY PLATEN
Jim Redmond and Susan Tucker Jan. 1995 39 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-AC04-94AL-85000)
(DE95-005493; SAND-94-2423) Avail: CASI HC A03

This report summarizes two approaches to time-optimal control of a nonlinear magnetically levitated platen. The system of interest is a candidate technology for next-generation photolithography machines used in the manufacture of integrated circuits. The dynamics and the variable peak control force of the electro-magnetic actuators preclude the direct application of classical time-optimal control methodologies for determining optimal rest-to-rest maneuver strategies. Therefore, this study explores alternate approaches using a previously developed computer simulation. In the first approach, conservative estimates of the available control forces are used to generate suboptimal switching curves. In the second approach, exact solutions are determined iteratively and used as a training set for an artificial neural network. The trained network provides optimal actuator switching times that incorporate the full nonlinearities of the magnetic levitation actuators. Sample problems illustrate the effectiveness of these techniques as compared to traditional proportional-derivative control. DOE

AFC GENERATOR DEVELOPMENT
B. L. Freeman, C. M. Fowler, M. G. Sheppard, and K. D. Sowder Feb. 1995 17 p
(Contract W-7405-eng-36)
(DE95-007094; LA-12860-MS) Avail: CASI HC A03/MF A01

By adapting the disk generator tested by Fowler, Hoeberling, and Marsh, the advanced flux compression (AFC) generator is able to produce a maximum dI/dt that is greater than 3 MA/microsecond. This current rise characteristic results in an inductive voltage across a 0.5-nH load of greater than or equal to 1.5 kV. This has been achieved with high gain, low loss, and a compact size. The AFC generator has been tested in four shots, and is performing beyond initial goals. DOE

LINEARLY TAPERED SLOT ANTENNA IMPEDANCE CHARACTERISTICS
Rainee N. Simons (NYMA, Inc., Brook Park, OH.) and Richard Q. Lee May 1995 6 p Presented at the IEEE/AP-S International Symposium and USNC/URSI Radio Science Meeting, Newport Beach, CA, 18-23 Jun. 1995; sponsored by the IEEE Antennas and Propagation Society and International Union of Radio Science
(RTOP 506-44-2C)
(NASA-TM-106912; E-9614; NAS 1.15:106912) Avail: CASI HC A02/MF A01

The paper presents for the first time an experimental technique to de-embed the input impedance of a LTSA from the measured reflection coefficient. The results show that the input impedance is dependent on the semi-flare angle and the length of the LTSA. The Re(Z(sub in)) is large when the electrical length of the LTSA is small and is on the order of few thousand ohms. However for an electrically large LTSA the Re(Z(sub in)) is in the range of 55 to 130 ohms. These results have potential applications in the design of broad band impedance matching networks for LTSA. DOE/KEURP SITE OPERATOR PROGRAM Second Quarter Report, 1 Oct. - 31 Dec. 1994
1994 22 p
(Contract DE-FC07-91ID-13074)
(DE95-007116; DOE/ID-13074/T14) Avail: CASI HC A03/MF A01

This is the 2nd quarter report of year four of the Kansas State University electric vehicle research program. Kansas State University (K-State), in support of the Department of Energy's and the Kansas Electric Utilities Research Program's subject contract, continues to demonstrate and develop electric vehicle and infrastructure technology. K-State is operating two Soleq's EVcort vehicles. During this reporting period both vehicles were returned to Chicago for warranty service. These vehicles have continued to operate and 'show' in a functional manner; however, one vehicle failed while being driven and the other vehicle's charger failed. It is expected that both vehicles will be returned to operational status within the early part of the next quarter. K-State continues to remain appraised of the issues surrounding the purchase of new technology S-10 electric pickup trucks, along with other Site Operator Program membership. K-State remains concerned that these vehicles may not ever arrive on site due to problems being discussed at this time. DOE

EVALUATION OF ALL-ELECTRIC SECONDARY POWER FOR TRANSPORT AIRCRAFT Final Report
W. E. Murray, L. J. Feiner, and R. R. Flores 24 Jan. 1992 311 p
(Contract NAS3-25965)
(NASA-CR-189077; NAS 1.26:189077; MDC-91K0418) Avail: CASI HC A14/MF A03

This report covers a study by Douglas Aircraft Company (DAC) of electrical power systems for advanced transport aircraft based upon an all-electric design concept. The concept would eliminate distributed hydraulic and pneumatic secondary power systems, and feature an expanded secondary electrical power system redesigned to supply power to the loads customarily supplied by hydraulic or pneumatic power. The initial study was based on an advanced 20-kHz electrical power transmission and distribution system, using a system architecture supplied by NASA-Lewis Research Center for twin-engine aircraft with many advanced power conversion concepts. NASA-LeRC later requested DAC to refocus the study on 400-Hz secondary power distribution. Subsequent work was based on a three-engine MD-11 aircraft, selected by DAC as a baseline system design that would provide data for the comparative cost/benefit analysis. The study concluded that the 20-kHz concept produced many expected benefits, and that the all-electric trijet weight savings on hardware redesign would be 2,304 pounds plus a 2.1-percent fuel reduction and resized for a total weight reduction of 11,000 pounds. Cost reductions for a fleet of 800 aircraft in a 15-year production program were estimated at $76.71 million for RDT&E; $2.74 million per aircrat for production; $9.84 million for nonrecurring expenses; $120,000 per aircraft for product support; and $300,000 per aircraft per year for operating and maintenance costs, giving a present value of $1.914 billion saved or a future value of $10.496 billion saved. A NUMERICAL STUDY OF ULTRA-SHORT-PULSE REFLECTOMETRY
B. I. Cohen, B. B. Afeyan, and A. E. Chou (California Univ., Los Angeles, CA.) May 1994 16 p Presented at the 10th Topical Conference on High-temperature Plasma Diagnostics, Rochester, NY, 8-12 May 1994
(Contracts W-7405-eng-48; DE-FG03-86ER-53225)
(DE95-008070; UCRL-JC-117939; CONF-940552-43) Avail: CASI HC A03/MF A01

Ultra-short-pulse reflectometry is studied by means of the numerical integration of a one-dimensional full-wave equation for ordinary modes propagating in a plasma. The numerical calculations illustrate the potential of using the reflection of ultra-short-pulse, microwaves as an effective probe of the density profile even in the presence of significant density fluctuations. The difference in time delays of differing frequency components of the microwaves can be used to deduce the density profile. The modification of the reflected pulses in the presence of density fluctuations is examined and can be understood based on considerations of Bragg resonance. A simple and effective profile-reconstruction algorithm using the zero-crossings of the reflected pulse and subsequent Abel inversion is demonstrated. The robustness of the profile reconstruction algorithm in the presence of a sufficiently small amplitude density perturbation is assessed. DOE

STABILITY MEASUREMENTS ON A 1-T HIGH TEMPERATURE SUPERCONDUCTING MAGNET
J. W. Lue, L. Dresner, S. W. Schwenterly, D. Aized (American Superconductor Corp., Westborough, MA.), J. M. Campbell (American Superconductor Corp., Westborough, MA.), and R. E. Schwall (American Superconductor Corp., Westborough, MA.) 1995 5 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007411; CONF-941013-24) Avail: CASI HC A01/MF A01

A high temperature superconducting magnet based on Bi-2223 conductor was built at the American Superconductor Corporation. The magnet was constructed by a react and wind technique using conductors made from a metallic precursor process. It was a winding ID of 25.4 mm, OD of 87.6 mm, and height of 107.3 mm. A heater, two thermometers, and several voltage taps were built into the high field region of the magnet for stability measurements. The magnet generates 1.1 T central field at 4.2 K when operating at 1 micro V/cm over the entire conductor length, including all the joints. Stability measurements were performed in background fields up to 2.5 T from 4.2 K to 77 K. Stability margins more than 2 orders of magnitude higher than a low temperature superconductor were observed. DOE

ELECTRIC VEHICLE ACTIVITIES Final Report, Sep. 1991 - Oct. 1994
J. L. DelMonaco and D. A. Pandya Feb. 1995 26 p
(Contract DE-FC07-91ID-13073)
(DE95-006648; DOE/ID-13073/1) Avail: CASI HC A03/MF A01

The data and information collected for the Public Service Electric and Gas Company's (PSE&G) electric vehicle demonstration program were intended to support and enhance DOE's Electric and Hybrid Vehicle Site Operator Program. The DOE Site Operator Program is focused on the life cycle and reliability of Electric Vehicles (EV's). Of particular interest are vehicles currently available with features that are likely to be put into production or demonstrate new technology. PSE&G acquired eight GMC Electric G-Vans in 1991, and three TEVans in 1993, and conducted a program plan to test and assess the overall performance of these electric vehicles. To accomplish the objectives of DOE's Site Operator's test program, a manual data collection system was implemented. The manual data collection system has provided energy use and mileage data. From September 1991 to October 1994 PSE&G logged 69,368 miles on eleven test vehicles. PSE&G also demonstrated the EVs to diverse groups and associations at fifty seven various events. Included in the report are lessons learned concerning maintenance, operation, public reactions, and driver's acceptance of the electric vehicles. DOE

STABILITY OF CHROMITE INTERCONNECTIONS IN DUAL ENVIRONMENTS
T. R. Armstrong, J. W. Stevenson, P. Raney, and L. R. Pederson Nov. 1994 5 p Presented at the Fuel Cell Seminar, San Diego, CA,28 Nov. - 1 Dec. 1994
(Contract DE-AC06-76RL-01830)
(DE95-007755; PNL-SA-25014; CONF-941109-1) Avail: CASI HC A01/MF A01

One of the most critical technical concerns in high-temperature SOFC's is the physical, chemical, and electrical stability of the interconnect (typically a doped lanthanum chromite) in the dual (oxidizing and reducing atmosphere) SOFC environment. The reducing or fuel side may experience oxygen partial pressures (P(O2)) from 10(exp -18) to 10(exp -6) atmospheres, while the oxidizing side may have P(O2) from 10(exp -6) to greater than 1 atm. These conditions limit the possible candidate materials to lanthanum or yttrium chromites. In the past decade, much work has centered on development of air-sinterable chromites and understanding their physical properties; little work, however, has focused on the stability of these chromites in dual environments. Chromite powders were synthesized using the glycine-nitrate process. The powders were calcined at 1,000 C for 1 hour and then uniaxially pressed into bars (46mm x 16mm x 3mm) at 55 MPa and isostatically pressed at 138 MPa. Samples were sintered in air. The dependence of the physical properties of sintered lanthanum chromites upon ambient P(O2) and temperature (using dilatometry, thermogravimetric analysis, and oxygen permeation measurements) were studied. La(1-x)A(x)CrO3 and Y(1-x)Ca(x)CrO3, where A is Ca or Sr and x was varied from 0.1 to 0.4 were evaluated in this study. The P(O2) was varied using a buffered CO2/Ar-4%H2 gas system, enabling expansion measurements to be made over a partial pressure range from 10(exp -5) to 10(exp -18) atmosphere at 800, 900, and 1,000 C. DEVELOPMENTS IN THE ELECTRON GUN SIMULATION PROGRAM, EGUN
W. B. Herrmannsfeldt Nov. 1994 6 p Presented at the Pulsed Radio Frequency Sources for Linear Colliders, Long Island, NY, 2-7 Oct. 1994
(Contract DE-AC03-76SF-00515)
(DE95-008137; SU-SLAC-PUB-6726; CONF-9410218-7) Avail: CASI HC A02/MF A01

This paper discusses the developments in the electron gun simulation programs that are based on EGUN with its derivatives and supporting programs. Much of the code development has been inspired by technology changes in computer hardware; the implications of this evolution on EGN2 are discussed. Some examples and a review of the capabilities of the EGUN family are described. DOE

NON-DESTRUCTIVE INTER-LEVEL DIELECTRIC VIA IN-LINE PROCESS MONITORING BY ATOMIC FORCE MICROSCOPY
A. J. Howard, A. G. Baca, and R. J. Shul 1994 5 p Presented at the 1995 GaAs Manufacturing Technology Conference, New Orleans, LA, 7-11 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008516; SAND-94-2823C; CONF-9505189-1) Avail: CASI HC A01/MF A01

A new application using atomic force microscopy (AFM) for in-line process control monitoring (PCM) of an interlevel dielectric via etching step is reported. The AFM with its near atomic-level resolution is capable of nondestructively measuring whether micron-sized vias have been etched to completion. Etch completion is determined by comparing the AFM measured etch depth of adjacent via holes through approximately 4000 (Angstrom) thick Si3N4 over Au-based ohmic and W gate metallizations. Due to etch selectivity, of the SF6/O2 reactive ion etch (RIIE) generated plasma, the ohmic metal acts as an etch stop whereas the W-based refractory gate continues to etch. For etch times beyond endpoint in the range of 20 to 50%, the AFM measured via etch depth differences is 250 to 400 (Angstrom) when comparing via depths over ohmic metal and W gate metal. This etch depth difference is a specific marker for etch completion and it is measured nondestructively at a point in the process where rework is still a feasible option. DOE

LOW-POWER, PARALLEL PHOTONIC INTERCONNECTIONS FOR MULTI-CHIP MODULE APPLICATIONS
R. F. Carson, M. L. Lovejoy, and K. L. Lear 1994 7 p Presented at the 45th Electronic Components and Technology Conference, Las Vegas, NV, 22-26 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008518; SAND-94-2878C; CONF-9505121-1) Avail: CASI HC A02/MF A01

New applications of photonic interconnects will involve the insertion of parallel-channel links into Multi-Chip Modules (MCM's). Such applications will drive photonic link components into more compact forms that consume far less power than traditional telecommunication data links. MCM-based applications will also require simplified drive circuitry, lower cost, and higher reliability than has been demonstrated currently in photonic and optoelectronic technologies. The work described is a parallel link array, designed for vertical (Z-Axis) interconnection of the layers in a MCM-based signal processor stack, operating at a data rate of 100 Mb/s. This interconnect is based upon high-efficiency VCSEL's, HBT photoreceivers, integrated micro-optics, and MCM-compatible packaging techniques. DOE

MULTIVARIATE CLASSIFICATION OF BPSG THIN FILMS USING MAHALANOBIS DISTANCES
S. Zhang (New Mexico Univ., Albuquerque, NM.), J. E. Franke (New Mexico Univ., Albuquerque, NM.), T. M. Niemczyk (New Mexico Univ., Albuquerque,

NM.), D. M. Haaland, J. N. Cox, I. Banerjee, J. Gee, T. Dang, and M. Puich 1995 7 p Presented at the 4th International Symposium on Diamond Materials, Reno, NV, 21-26 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008519; SAND-95-0394C; CONF-9505192-1) Avail: CASI HC A02/MF A01

Infrared absorption spectra of borophosphosilicate glass (BPSG) thin films were collected to develop a rapid classification method for determining if the films are within the desired specifications. Classification of samples into good and bad categories was performed using principal component analysis applied to the spectra. Mahalanobis distances were used as the classification metric. The highest overall percentage of correct classification of samples based upon their spectra was 91.6%. DOE

POLARIZATION RELAXATION IN ZINC OXIDE VARISTORS FROM 77 K TO 450 K
R. W. Major, A. E. Werner, C. B. Wilson, and F. A. Modine Oct. 1994 13 p Presented at the 96th Annual Meeting of the American Ceramic Society (ACS), Indianapolis, IN, 25-28 Apr. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007761; CONF-940416-33) Avail: CASI HC A03/MF A01

The time and temperature dependences of polarization currents are investigated to higher temperatures and with greater temperature resolution than has been reported previously for zinc oxide varistors. Arrhenius plots yield thermal activation energies near 140 and 8 MeV, which are in reasonable agreement with values reported recently, as well as an additional thermally activated level at 0.66 eV, which emerges in the extension of the measurements to T greater than 300 K. Conductance data in this higher temperature range for the same samples yield the nearly identical energy of 0.68 eV for the intergranular (Schottky) barrier height. The temperature dependence of the exponent m in the power-law expression for the current-time dependence I = I(sub o)t(sup -m) was carefully examined and found to change twice from 0.5 to 1.0. The non-monotonic behavior of m with temperature is interpreted as due to resolution of the polarization currents from two different traps each of which makes the transition from diffusive to dispersive transport as temperature is lowered rather than, for example, a complicated distribution of relaxation times. THE DETERMINATION OF THE CONSTITUTIVE PARAMETERS OF A MEDIUM WITH APPLICATION TO A REINFORCED CONCRETE PAD
A. J. Poggio, G. L. Burke, and S. T. Pennock Jun. 1995 58 p
(NASA Order L-79902-C; RTOP 538-01-13-01)
(NASA-CR-4674; NAS 1.26:4674; UCRL-CR-120519) Avail: CASI HC A04/MF A01

This report describes the experimental and analytical efforts performed to determine the constitutive parameters of a reinforced concrete pad on which an aircraft (the NASA Boeing 757) was parked while its internal electromagnetic environment was measured. This concrete pad is part of the Large Electromagnetic System-Level Illuminator (LESLI) test facility at the Phillips Laboratory, Kirtland Air Force Base, New Mexico. The relative dielectric constant, conductivity, index of refraction, and reflection coefficient have been determined over the frequency range of 0 to 300 MHz and are presented. Author

THEORY OF EXOTIC SUPERCONDUCTIVITY AND NORMAL STATES OF HEAVY ELECTRON AND HIGH TEMPERATURE SUPERCONDUCTIVITY MATERIALS Progress Report, 15 Feb. 1994 - - 14 Feb. 1995
D. L. Cox 1995 6 p
(Contract DE-FG02-87ER-45326)
(DE95-006637; DOE/ER-45326/T5) Avail: CASI HC A02/MF A01

This is a progress report for the DOE project covering the period 2/15/94 to 2/14/95. The PI had a fruitful sabbatical during this period, and had some important new results, particularly in the area of new phenomenology for heavy fermion superconductivity. Significant new research accomplishments are in the area of odd-in-time-reversal pairing states/staggered superconductivity, the two-channel Kondo lattice, and a general model for Ce impurities which admits one-, two-, and three-channel Kondo effects. Papers submitted touch on these areas: staggered superconductivity - a new phenomenology for UPt(sub 3); theory of the two-channel Kondo lattice in infinite dimensions; general model of a Ce(3+) impurity. Other work was done in the areas: Knight shift in heavy fermion alloys and compounds; symmetry analysis of singular pairing correlations for the two-channel Kondo impurity model. DOE

LITHIUM ION RECHARGEABLE SYSTEMS STUDIES
Samuel C. Levy, Robert R. Lasasse, Randall T. Cygan, and James A. Voigt 1995 6 p Presented at the 12th International Seminar on Primary and Secondary Battery Technology and Application, Deerfield Beach, FL, 6-8 Mar. 1995
(Contract DE-AC04-94AL-85000)
(DE95-006810; SAND-95-0157C; CONF-950312-1) Avail: CASI HC A02/MF A01

Lithium ion systems, although relatively new, have attracted much interest worldwide. Their high energy density, long cycle life and relative safety, compared with metallic lithium rechargeable systems, make them prime candidates for powering portable electronic equipment. Although lithium ion cells are presently used in a few consumer devices, e.g., portable phones, camcorders, and laptop computers, there is room for considerable improvement in their performance. Specific areas that need to be addressed include: (1) carbon anode-increase reversible capacity, and minimize passivation; (2) cathode-extend cycle life, improve rate capability, and increase capacity. There are several programs ongoing at Sandia National Laboratories which are investigating means of achieving the stated objectives in these specific areas. This paper will review these programs. OBIC ANALYSIS OF STRESSED, THERMALLY-ISOLATED POLYSILICON RESISTORS
Edward I. Cole, Jr., Kenneth A. Peterson, Ann N. Campbell, Eric S. Snyder, Donald G. Pierce, John S. Suehle (National Inst. of Standards and Technology, Gaithersburg, MD.), and Prasad Chaparala (Maryland Univ., College Park, MD.) 1994 10 p Presented at the International Reliability Physics Symposium, Las Vegas, NV, 3-6 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008511; SAND-94-2464C; CONF-950432-1) Avail: CASI HC A02/MF A01

High gain Optical Beam Induced Current (OBIC) imaging has been used for the first time to examine the internal structural effects of electrical stress on thermally-isolated polysilicon resistors. The resistors are examined over a wide range of current densities, producing Joule heating up to (approximately) 1200 C. Throughout this current density range, the OBIC images indicate a clustering of dopant under dc stress and a more uniform distribution under ac conditions. The OBIC images also reveal areas that are precursors to catastrophic resistor failure. In addition to OBIC imaging, conventional electrical measurements were performed, examining the polysilicon resistance degradation and time-to-failure as a function of electrical stress. The electrical measurements show a monotonic increase in polysilicon resistor lifetime with frequency (up to 2 kHz) when subjected to a bipolar ac stress. The enhanced lifetime was observed even under high temperature (from Joule heating) stress conditions previously reported to be electromigration-free. The dopant redistribution indicated by the OBIC images is consistent with an electromigration stress experienced by the polysilicon resistors. The implications for thermally-isolated polysilicon resistor reliability are examined briefly. DOE

JTEC PANEL REPORT ON MICROELECTROMECHANICAL SYSTEMS IN JAPAN Final Report
Kensall D. Wise (Michigan Univ., Ann Arbor, MI.), Richard S. Muller (California Univ., Berkeley, CA.), Henry Guckel (Wisconsin Univ., Madison, WI.), Joseph M. Giachino (Ford Motor Co., Dearborn, MI.), G. Benjamin Hocker (Honeywell, Inc., Bloomington, MN.), and Stephen C. Jacobsen (Utah Univ., Salt Lake City, UT.) Sep. 1994 311 p
(Grant NSF ENG-92-17849)
(NASA-CR-197831; NAS 1.26:197831; PB95-100244; ISBN-1-883-712-35-1) Avail: CASI HC A14/MF A03

This report summarizes recent activities in the development of microelectromechanical systems (MEMS) in Japan. For the purposes of this study, 'MEMS' means batch-fabricated miniature devices that convert physical parameters to or from electrical signals and that depend on mechanical structures or parameters in important ways for their operation. The report covers advanced materials and process technology; sensors and sensing microstructures; microactuators and actuation mechanisms; sensor-circuit integration and system partitioning; advanced packaging, microassembly, and testing technologies; and MEMS design techniques, applications, and infrastructure. The panel found that Japanese industry is emphasizing approaches to MEMS that are similar to those taken by U.S. industry (i.e., approaches based on silicon integrated-circuit technology); these efforts are comparable in their level of development to those in the United States. However, the ten-year, $250 million, MITI-sponsored program in micromachines emphasizes the miniaturization of more traditional (nonlithographic) machining processes, an area in which there is no comparable U.S. effort. Packaging technology and applications for batch-fabricated MEMS devices is considered a major challenge in both countries. The panel concluded that these and other issues will require global leadership and international cooperation to realize the benefits of MEMS in a timely way. Author

LOW NOISE MONOLITHIC SI JFETS FOR OPERATION IN THE 90-300K RANGE AND IN HIGH RADIATION ENVIRONMENTS
V. Radeka, M. Citterio, S. Rescia, P. F. Manfredi (Pavia Univ., Italy.), and V. Speziali (Pavia Univ., Italy.) Dec. 1994 3 p Presented at the Low Temperature Electronics and High Temperature Superconductivity Conference, Reno, NV, 21-26 May 1995
(Contract DE-AC02-76CH-00016)
(DE95-007303; BNL-61328; CONF-9505163-1) Avail: CASI HC A01/MF A01

Development of low noise preamplifiers for large ionization chambers with liquid argon (LAr) and liquid krypton (LKr) used in high energy physics experiments for measurement of energy of charged particles and photons requires die choice of a technology able to withstand the environment: a temperature of 90-120 K; an ionizing radiation dose of 1-2 Mrad; a neutron fluence of 0.5-1.10(exp 14)n/sq cm. Silicon JFET's (junction field effect transistors) by virtue of their reliable noise behavior and their intrinsic radiation hardness appear to be very suitable devices for applications both at room and cryogenic temperatures. We describe the noise properties of JFET devices and a monolithic preamplifier suitable for amplification of charge and current signals. DOE

FIELD QUALITY IMPROVEMENTS IN SUPERCONDUCTING MAGNETS FOR RHIC
R. Gupta, A. Jain, S. Kahn, G. Morgan, P. Thompson, P. Wanderer, and E. Willen 1994 3 p Presented at the 4th European Particle Accelerator Conference, London, England, 27 Jun. - 1 Jul. 1994
(Contract DE-AC02-76CH-00016)
(DE95-006096; BNL-60352; CONF-940618-117) Avail: CASI HC A01/MF A01

A number of techniques have been developed and tested to improve the field quality in the superconducting dipole and quadrupole magnets to be used in the Relativistic Heavy Ion Collider (RHIC). These include adjustments in the coil midplane gap to compensate for the allowed and non-allowed harmonics, inclusion of holes and cutouts in the iron yoke to reduce the so harmonics, and magnetic tuning shims to correct for the residual errors. We compare the measurements with the calculations to test the validity of these concepts. DOE

Int-Patent-Class-G05F-1/613; Int-Patent-Class-H02M-3/335) Avail: US Patent and Trademark Office

A pulse-width modulated DC-to-DC power converter including a first inductor, i.e. a transformer or an equivalent fixed inductor equal to the inductance of the secondary winding of the transformer, coupled across a source of DC input voltage via a transistor switch which is rendered alternately conductive (ON) and nonconductive (OFF) in accordance with a signal from a feedback control circuit is described. A first capacitor capacitively couples one side of the first inductor to a second inductor which is connected to a second capacitor which is coupled to the other side of the first inductor. A circuit load shunts the second capacitor. A semiconductor diode is additionally coupled from a common circuit connection between the first capacitor and the second inductor to the other side of the first inductor. A current sense transformer generating a current feedback signal for the switch control circuit is directly coupled in series with the other side of the first inductor so that the first capacitor, the second inductor and the current sense transformer are connected in series through the first inductor. The inductance values of the first and second inductors, moreover, are made identical. Such a converter topology results in a simultaneous voltsecond balance in the first inductance and ampere-second balance in the current sense transformer.

DEVELOPMENT OF AN ULTRA-SAFE RECHARGEABLE LITHIUM-ION BATTERY Status Report, 15 Aug. - 15 Nov. 1994
J. K. Jacobs 15 Nov. 1994 4 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-C-0141)
(AD-A288959) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The project activities had an official start on August 15. Based on previous work, a statement of the basic design framework to be used was an important first step. The basic cell is to be a bonded flat-pack containing all active cell components in a sealed envelope. Cell integrity is to be provided by internal bonding, and not through external support. This design approach is fundamentally different from that commonly used in wound and hard-case cells, and has the advantage of ease of scaling for a variety of different form factors. An innovative variant on the fan-fold geometry has been chosen for its manufacturability advantages. Equipment capable of handling the semi-continuous requirements of the fan-fold structure had already been outlined. There are specific advantages in at least three areas: (1) Control of dimensional tolerances; (2) Production rate; (3) Connection of power lead-outs and final assembly. Cell chemistry is viewed to be of less fundamental importance than structural considerations within the bounds of the lithium-ion concept. DTIC

THERMAL ANALYSIS OF PANSAT BATTERIES AND ELECTRICAL POWER SUBSYSTEM M.S. Thesis
Sheila A. Patterson Sep. 1994 203 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A290013) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The thermal design of a spacecraft ensures proper heat transfer so all components and subsystems remain within prescribed temperature limits during all aspects of the spacecraft's mission. This thesis develops a point to-point heat flow model of the Electrical Power Subsystem (EPS) and its associated housing for the Petite Amateur Navy Satellite (PANSAT). This analysis was performed to identify physical locations in the EPS where temperatures may exceed the limits established to protect sensitive electronic components, and to define the expected environment of the batteries. The Integrated Thermal Analysis System (ITAS) and a Steady State Thermal Analyzer and Model Builder were used to perform steady state and transient analyses on the EPS: analysis of the batteries was performed using ITAS only. The simulated transient temperatures within the EPS housing remained within limits, but the batteries exceeded specifications. It is suggested that a passive thermal control technique be adapted for the batteries and its design be experimentally validated before flight. DTIC

MEASUREMENT-BASED MESFET MODEL IN APLAC
M. Laehepelto and M. Valtonen Oct. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-195483; ISBN-951-22-2348-1) Avail: CASI HC A03

A measurement-based MESFET model is presented where the large-signal model is constructed from measured small-signal S parameters and DC currents. The S parameters are measured at various frequencies and converted to Y parameters using nth order Chebyshev power series expansion. The nonlinear static, dynamic, and higher-order components in the model are created with the aid of line integration over the voltage waveforms. The nonlinear large-signal model proposed is valid for a very wide bias range, and may also be used in the time domain. The model as well as the model extractor are implemented in Analysis Program for Linear Active Circuits (APLAC). NTIS

The research described in this report was based on concepts advanced earlier by Dr. James W. Mink, then of the Army Research Office. His analyses for quasi-optical power combining from solid-state source arrays have formed a strong basis for a number of investigations in this field in recent years. Previous studies dealt with microwave arrays, while the present one was the first to deal with millimeter-wave arrays of FET's and HEMT's. Dr. Mink served as the A.R.O. technical monitor for the majority of this project, and the authors would like to express appreciation for his advice and contributions. DTIC

EVALUATION OF DEFECT-RELATED DIFFUSION IN SEMICONDUCTORS BY ELECTROOPTICAL SAMPLING
Paul Biernacki, Henry Lee, and Alan R. Mickelson 15 Feb. 1995 48 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-92-J-1190; DAAL03-92-G-0289)
(AD-A291630; ECE/CWOL/67) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The electrooptical sampling technique is used to assess the electrical behavior of ohmic contact regions in GaAs. For purpose, unique ohmic contact coplanar waveguides were fabricated and tested. A reduced electrooptical sampling signal is detected in certain ohmic contact regions. Since the electrical fields present in this device are known a priori, the deviation of the electrooptical signal from its nominal value is attributed to a deviation in the electrooptical coefficient. Defects introduced during the annealing step of the ohmic contact accelerated by existing dislocations are discussed as a mechanism capable of disrupting the electrooptic coefficient. A simple phenomenological diffusion model is presented to explain the mechanism responsible for the nulling of the electrooptical coefficient. DTIC

Avail: CASI HC A07/MF A02

Modeling of interconnects and associated discontinuities with the recent advances high-speed digital circuits has gained a considerable interest over the last decade although the theoretical bases for analyzing these structures were well-established as early as the 1960s. Ongoing research at the present time is focused on devising methods which can be applied to more general geometries than the ones considered in earlier days and, at the same time, improving the computational efficiency and accuracy of these methods. In this thesis, numerically efficient methods to compute the transmission line parameters of a multiconductor system and the equivalent capacitances of various strip discontinuities are presented based on the quasi-static approximation. The presented techniques are applicable to conductors embedded in an arbitrary number of dielectric layers with two possible locations of ground planes at the top and bottom of the dielectric layers. The cross-sections of conductors can be arbitrary as long as they can be described with polygons. An integral equation approach in conjunction with the collocation method is used in the presented methods. A closed-form Green's function is derived based on weighted real images thus avoiding nested infinite summations in the exact Green's function; therefore, this closed-form Green's function is numerically more efficient than the exact Green's function. All elements associated with the moment matrix are computed using the closed-form formulas. Various numerical examples are considered to verify the presented methods, and a comparison of the computed results with other published results showed good agreement. Author

A detection method and system utilizing silicon models of the traveling wave structure of the human cochlea to spatially and temporally locate a specific sound source in the presence of high noise pandemonium. The detection system combines two-dimensional stereausis representations, which are output by at least three VLSI binaural hearing chips, to generate a three-dimensional stereausis representation including both binaural and spectral information which is then used to locate the sound source.

ENERGY-MEASURING RESISTOR BANK Patent
Anthony M. Marques, inventor (to Navy), Paul R. Kelley, inventor (to Navy), William K. Jones, inventor (to Navy), and Masatoshi Fuk, inventor (to Navy) 16 Aug. 1994 5 p Filed 30 Mar. 1993
(AD-D017392; US-Patent-5-339,066; US-Patent-Appl-SN-045340; US-Patent-Class-338-306) Avail: US Patent and Trademark Office

A resistor bank consisting of a group of resistors formed on the surface of a die, all electrically connected together in parallel. All of the resistors have identical individual resistances, but each has a unique energy dissipating capacity. When an event subjects the resistor bank to a surge of current, some of the resistors blow out, thereby changing the resistance of the bank. By measuring the resistance of the bank before and after an event the energy of the surge can be determined. DTIC

NON-LINEAR RESISTIVE GRID KERNEL ESTIMATOR USEFUL IN SINGLE FEATURE, TWO-CLASS PATTERN CLASSIFICATION Patent
Jeffrey L. Solka, inventor (to Navy), George W. Rogers, inventor (to Navy), Carey E. Priebe, inventor (to Navy), Wendy L. Poston, inventor (to Navy), and Harold Szu, inventor (to Navy) 15 Nov. 1994 6 p Filed 26 Nov. 1993
(AD-D017394; US-Patent-5-365,472; US-Patent-Appl-SN-157553; US-Patent-Class-364-807) Avail: US Patent and Trademark Office

A discrete non-linear estimator is provided to establish a probability density function useful in classification of a feature as belonging to one of two classes. A first and second known feature space associated with respective first and second classes are each converted to a plurality of voltages reflecting corresponding first and second feature space bins. A first and second one-dimensional, non-linear resistive grid has input nodes that continuously receive the voltages reflecting the respective first and second known feature space. Each resistive grid produces an output voltage at each of a corresponding plurality of first and second output nodes. Each of a plurality of voltage comparators are used to compare voltages at corresponding first and second output nodes to output a discrete probability density function that considers corresponding ones of the first and second feature space bins. A display may be used to visually or otherwise provide each probability density function from each voltage comparator. DTIC

NOVEL FIELD EFFECT TRANSISTORS FOR LOW POWER ELECTRONICS Progress Report No. 3
16 Jan. 1995 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-C-0260)
(AD-A289929) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The primary objective of this Phase 1 project is to determine the extent of the significant reduction in power consumption of integrated circuits which may be achieved by utilizing a novel sidegate FET technology. The new FET technology promises to eliminate the Narrow Channel Effect (NCE) which is one of the primary factors limiting the minimum power consumption of integrated circuits. Bv eliminating the NCE, we will be able to scale the device size dramatically and reduce the power consumption by an order of magnitude. The project will assess the power, speed, circuit design, processing, and manufacturability of the new FET technology for both digital and analog circuit applications. In particular, we will extract device parameters from the new ultra-low power FET's fabricated at UVA to develop device models, incorporate these models into a new SPICE package (AIM-SPICE), simulate different logic families including DCFL and SCFL, and compare the predicted performance with the standard DCFL and SCFL logic. We will also analyze the gate current leakage and subthreshold slope as the primary factors limiting the noise margins at low power supplies, establish the minimum required bias voltage for reliable operation, and analyze the factors determining the threshold voltage changes from device to device as well as other factors which may limit the yield and integration scale. STRUCTURAL OPTIMISATION OF CAGE INDUCTION MOTORS USING FINITE ELEMENT ANALYSIS Thesis
S. Palko 1994 61 p
(PB95-195434; ISBN-951-22-2392-9) Avail: CASI HC A04/MF A01

The current trend in motor design is to have highly efficient, low noise, low cost, and modular motors with a high power factor. High torque motors are useful in applications like servo motors, lifts, cranes, and rolling mills. This report contains a detailed review of different optimization methods applicable in various design problems. Special attention is given to the performance of different methods, when they are used with finite element analysis (FEA) as an objective function, and accuracy problems arising from the numerical simulations. Also an effective method for designing high starting torque and high efficiency motors is presented. The method described in this work utilizes FEA combined with algorithms for the optimization of the slot geometry. The optimization algorithm modifies the position of the nodal points in the element mesh. The number of independent variables ranges from 14 to 140 in this work. NTIS

A FULLY IMPLICIT TIME ACCURATE METHOD FOR HYPERSONIC COMBUSTION: APPLICATION TO SHOCK-INDUCED COMBUSTION INSTABILITY
Shaye Yungster and Krishnan Radhakrishnan (NYMA, Inc., Brook Park, OH.) Aug. 1994 16 p Presented at the 30th Joint Propulsion Conference, Indianapolis, IN, 27-29 Jun. 1994; cosponsored by AIAA, ASME, SAE, and ASEE
(Contracts NAS3-27186; NCC3-233; RTOP 505-90-5K)
(NASA-TM-106707; ICOMP-94-18; E-9069; NAS 1.15:106707; AIAA Paper 94-2965) Avail: CASI HC A03/MF A01

A new fully implicit, time accurate algorithm suitable for chemically reacting, viscous flows in the transonic-to-hypersonic regime is described. The method is based on a class of Total Variation Diminishing (TVD) schemes and uses successive Gauss-Siedel relaxation sweeps. The inversion of large matrices is avoided by partitioning the system into reacting and nonreacting parts, but still maintaining a fully coupled interaction. As a result, the matrices that have to be inverted are of the same size as those obtained with the commonly used point implicit methods. In this paper we illustrate the applicability of the new algorithm to hypervelocity unsteady combustion applications. We present a series of numerical simulations of the periodic combustion instabilities observed in ballistic-range experiments of blunt projectiles flying at subdetonative speeds through hydrogen-air mixtures. The computed frequencies of oscillation are in excellent agreement with experimental data. Author

COMPUTATIONAL FLUID DYNAMICS AND TRANSONIC FLOW Final Technical Report, 1 Oct. 1990 - 30 Sep. 1994
Paul R. Garabedian 31 Oct. 1994 6 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0042-91)
(AD-A288962; AFOSR-94-0760TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The project was concerned with the development of high performance computer codes for problems in transonic aerodynamics. A practical rule to calculate the wave drag for solutions of the Euler equations was developed from an entropy equality. Symmetric shockless airfoils were analyzed for which uniqueness fails in the transonic case not just for potential flow, but also for the Euler equations. DTIC

A NON-ITERATIVE GRID DEFORMATION ALGORITHM FOR COMPUTATIONAL FLUID DYNAMICS FOR AEROELASTICITY Interim Report, Jun. - Jul. 1994
Richard D. Synder Sep. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AF Proj. 2401)
(AD-A288298; WL-TM-94-3130) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This Technical Memorandum presents an algorithm for deforming a two- or three-dimensional aerodynamic grid given deflections on a physical boundary. This algorithm is to be used in coupling a computational fluid dynamics code with a computational structural mechanics code. The deformation algorithm was tested successfully on both two- and three-dimensional grids. The method sufficiently maintains grid quality for smooth deflections of realistic orders of magnitude. The method is computationally efficient: the time required to deform the grid is small compared to the time required to solve the fluid dynamics. DTIC

A FIXED TIME PERFORMANCE EVALUATION OF PARALLEL CFD APPLICATIONS
A. M. Baker and S. X. Ying (Ames Lab., IA.) 1994 14 p Presented at the Supercomputing '94 Meeting, Washington, DC, 14-18 Nov. 1994
(Contract W-7405-eng-82)
(DE94-014240; IS-M-790; CONF-941118-3) Avail: CASI HC A03/MF A01

The inviscid gas dynamics equations have been solved on the nCUBE 2s computer to better understand the challenges and opportunities that parallel processing presents. Two basic computational fluid dynamics applications problems representing different flow physics are used as test cases. The first problem involves a supersonic flow inside a channel with a ramp surface. This internal flow problem is dominated by large gradients due to shock waves reflected between channel walls. The equations solved are coupled nonlinear hyperbolic partial differential equations. The second problem is an external flow over airfoil. The flow is subsonic, resulting in a set of elliptic pdes. Analysis of the parallel performance for these applications is presented following a fixed time measurement approach. The results from this study demonstrate that even though these flow simulation problems are communication intensive, they are scalable. This is true even if subdomain communication includes non-nearest neighbors. Parallel computing is shown to be an effective tool for future CFD challenges. DOE

WAVENUMBER SELECTION FOR SMALL-WAVELENGTH GOERTLER VORTICES IN CURVED CHANNEL FLOWS Final Report
Andrew Dando (Manchester Univ., England.) and Philip Hall (Manchester Univ., England.) Apr. 1995 29 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-195063; NAS 1.26:195063; ICASE-95-21) Avail: CASI HC A03/MF A01

The problem of wavenumber selection for fully nonlinear, small-wavelength Goertler vortices in a curved channel flow is considered. These types of Goertler vortices were first considered by Hall & Lakin

(1988) for an external boundary layer flow. They proved particularly amenable to asymptotic description, it was possible to consider vortices large enough so that the mean flow correction driven by them is as large as the basic state, and this prompted the authors to consider them in a curved channel flow as an initial application of the phase-equation approach to Goertler vortices. This involves the assumption that the phase variable of these Goertler vortices varies on slow spanwise and time scales, then an analysis of both inside and outside the core region, to which vortex activity is restricted, leads to a system of partial differential equations which can be solved numerically for the wavenumber. The authors consider in particular the effect on the wavenumber of the outer channel wall varying on the same slow spanwise scale as the phase variable. Author

(NASA-CR-197758; NAS 1.26:197758; MCAT-95-15) Avail: CASI HC A03/MF A01; 1 functional color page

The purpose of this project has been to identify and test suitable technologies for implementation of fluid flow solvers -- possibly coupled with structures and heat equation solvers -- on MIMD parallel computers. In the course of this investigation much attention has been paid to efficient domain decomposition strategies for ADI-type algorithms. Multi-partitioning derives its efficiency from the assignment of several blocks of grid points to each processor in the parallel computer. A coarse-grain parallelism is obtained, and a near-perfect load balance results. In uni-partitioning every processor receives responsibility for exactly one block of grid points instead of several. This necessitates fine-grain pipelined program execution in order to obtain a reasonable load balance. Although fine-grain parallelism is less desirable on many systems, especially high-latency networks of workstations, uni-partition methods are still in wide use in production codes for flow problems. Consequently, it remains important to achieve good efficiency with this technique that has essentially been superseded by multi-partitioning for parallel ADI-type algorithms. Another reason for the concentration on improving the performance of pipeline methods is their applicability in other types of flow solver kernels with stronger implied data dependence. Analytical expressions can be derived for the size of the dynamic load imbalance incurred in traditional pipelines. From these it can be determined what is the optimal first-processor retardation that leads to the shortest total completion time for the pipeline process. Theoretical predictions of pipeline performance with and without optimization match experimental observations on the iPSC/860 very well. Analysis of pipeline performance also highlights the effect of uncareful grid partitioning in flow solvers that employ pipeline algorithms. If grid blocks at boundaries are not at least as large in the wall-normal direction as those immediately adjacent to them, then the first processor in the pipeline will receive a computational load that is less than that of subsequent processors, magnifying the pipeline slowdown effect. Extra compensation is needed for grid boundary effects, even if all grid blocks are equally sized. Derived from text

NUMERICAL SIMULATION OF THE SOFIA FLOW FIELD Final Report
Stephen P. Klotz Jan. 1995 99 p
(Contract NCC2-636)
(NASA-CR-197757; NAS 1.26:197757; MCAT-95-08) Avail: CASI HC A05/MF A02

This report provides a concise summary of the contribution of computational fluid dynamics (CFD) to the SOFIA (Stratospheric Observatory for Infrared Astronomy) project at NASA Ames and presents results obtained from closed- and open-cavity SOFIA simulations. The aircraft platform is a Boeing 747SP and these are the first SOFIA simulations run with the aircraft empennage included in the geometry database. In the open-cavity runs the telescope is mounted behind the wings. Results suggest that the cavity markedly influences the mean pressure distribution on empennage surfaces and that 110-140 decibel (db) sound pressure levels are typical in the cavity and on the horizontal and vertical stabilizers. A strong source of sound was found to exist on the rim of the open telescope cavity. The presence of this source suggests that additional design work needs to be performed in order to minimize the sound emanating from that location. A fluid dynamic analysis of the engine plumes is also contained in this report. The analysis was part of an effort to quantify the degradation of telescope performance resulting from the proximity of the port engine exhaust plumes to the open telescope bay. Author

SUPG FINITE NUMERICAL ELEMENT SOLUTIONS FOR NON-COMPRESSIBLE NAVIER-STOKES EQUATION SETS
Guoqun Xu and Guofu Zhang 15 Nov. 1994 17 p Transl. into ENGLISH from Kongqidonglixue Xuebao (China), v. 9, no. 3, Sep. 1991 p 372-378 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289600; NAIC-ID(RS)T-0917-92) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This article sets out from steady state non-compressible Navier-Stokes equation sets and constructs weighted residual SUPG formulations. In order to guarantee the precision of numerical value solutions, this article -- with regard to speeds -- selects eight points for the interpolation of values and maintains the second order derivative quantities in perturbation terms. Looking from the point of view of calculation instances made using the methods of this article, the calculated results have proved very satisfying. DTIC

VISCOUS SHOCK-LAYER ANALYSIS ON HYPERSONIC FLOW OVER REENTRY CAPSULE WITH NONEQUILIBRIUM CHEMISTRY
Kojiro Suzuki and Takashi Abe Dec. 1994 20 p Repr. from Institute of Space and Astronautical Science Report No. 656 (Sagamihara, Japan, Tokyo Univ.), Dec. 1994 p 1-17
(ISSN 0285-6808)
(ISAS-R-656) Avail: CASI HC A03/MF A01

The aerothermodynamic environment around a 'EXPRESS' reentry capsule at hypersonic speed is studied in the flight regime of the severe wall heating rate with emphasis on the effects of the wall catalycity and temperature by using the axisymmetric viscous shock-layer equations with the seven-air-species nonequilibrium chemistry. The wall heating rate and the electron number density in the shock-layer over the capsule are predicted at various altitudes on its flight trajectory. In order to evaluate the wall catalycity, the finite catalytic wall model is introduced. The sensitivity of the wall heating rate to the uncertainties in the chemical reaction model and the wall condition model is investigated parametrically. The extent of the influences of the wall conditions on the shock-layer flow properties strongly depends on the extent of flow nonequilibrium. Author

STATISTICAL MODEL FOR MOLECULAR INTERNAL ENERGY EXCHANGE IN DSMC METHOD FOR RAREFIED FLOW ANALYSIS
Takashi Abe Nov. 1994 12 p Repr. from Institute of Space and Astronautical Science Report No. 654 (Sagamihara, Japan, Tokyo Univ.), Nov. 1994 p 1-9
(ISSN 0285-6808)
(ISAS-R-654) Avail: CASI HC A03/MF A01

New statistical direct simulation Monte Carlo model for internal energy exchange for molecules is proposed. The derivation of the model is based on the inelastic collision cross section which ensures the relation of detailed balance at equilibrium between microscopic states. It is shown that the present derivation method gives us a general frame-work to generate various models for the inelastic collision. The present derivation method can generate not only the present internal energy exchange model but also the Koura's inelastic cross-section model. The present internal energy exchange model was applied to an adiabatic thermal relaxation problem in a stationary reservoir and was compared with Koura's statistical inelastic cross-section model. ANOMALOUS COLLISION RATE IN THE TIME COUNTER SCHEME OF THE DIRECT SIMULATION MONTE CARLO METHOD FOR RAREFIED GAS FLOW ANALYSIS
Takashi Abe Nov. 1994 17 p Repr. from Institute of Space and Astronautical Science Report No. 653 (Sagamihara, Japan, Tokyo Univ.), Nov. 1994 p 1-14
(ISSN 0285-6808)
(ISAS-R-653) Avail: CASI HC A03/MF A01

In the direct simulation Monte Carlo method (DSMC), it is shown that a widely used time counter (TC) scheme proposed by Bird gives inaccurate results for certain non-equilibrium distribution functions. The functions are defined in the text and include as an extreme case the distribution function of the cold counter-streaming flow. When the TC scheme is applied to these distribution functions it results in counting a rate of collision too largely, and there is consequently a corresponding error in advancing the simulation time. This effect appears in functions which differ from the equilibrium one by more than a certain threshold amount. The threshold is shown to depend on the number of particles being simulated, and increases with their number. That is, the applicability of the TC scheme increases with particle numbers. A new scheme based on the collision rate is proposed to overcome the difficulty with the TC scheme. The CPU time of the new scheme is proportional to the particle numbers and is comparable to both the TC scheme and the no-time counter scheme in computation efficiency. Author

DEMONSTRATION STUDY OF HIERARCHICAL CONTROL OF FLUID-DYNAMIC PHENOMENA Final Report
Gregory A. Reynolds and Edward Hensel 20 Dec. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-3018)
(AD-A289341) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This document is a final report for ONR grant N00014-89-J-3018, 'Demonstration Study of Hierarchical Control of Fluid-Dynamic Phenomena.' Our overall objective was to develop a laboratory experiment wherein the performance of a fluid dynamic process would be effectively controlled using a model-based system controller. We considered, as a sample fluid-dynamic process, the flow over a high-lift circulation-control wing. The essence of our model-based approach was a progression of fluid-dynamic models corresponding to the expected range of complexity in the attached and separated flow of the experiment. Development of the demonstration involved both fabrication and testing of the high-lift wing model and test apparatus, as well as coding and evaluation of the control algorithms and fluid-dynamic models. preparatory to this development, a flow facility in which to conduct the experiments had to be designed and constructed. Unfortunately, due to delays in completion of this facility, the demonstration experiments could not be carried out within the budget of the grant. Our overall objective was therefore not met, however, we will report here on the substantial progress we did make to establish the capabilities cited above. DTIC

PROGRESS IN INCOMPRESSIBLE NAVIER-STOKES COMPUTATIONS FOR PROPULSION FLOWS AND ITS DUAL-USE APPLICATIONS Final Report
Cetin Kiris Jan. 1995 37 p Original contains color illustrations
(Contract NCC2-500)
(NASA-CR-197746; NAS 1.26:197746; MCAT-95-02) Avail: CASI HC A03/MF A01; 7 functional color pages

Development of an incompressible Navier-Stokes solution procedure was performed for the analysis of a liquid rocket engine pump components and for the mechanical heart assist devices. The solution procedure for the propulsion systems is applicable to incompressible Navier-Stokes flows in a steadily rotating frame of reference for any general complex configurations. The computer codes were tested on different complex configurations such as liquid rocket engine inducer and impellers. As a spin-off technology from the turbopump component simulations, the flow analysis for an axial heart pump was conducted. The baseline Left Ventricular Assist Device (LVAD) design was improved by adding an inducer geometry by adapting from the liquid rocket engine pump. The time-accurate mode of the incompressible Navier-Stokes code was validated with flapping foil experiment by using different domain decomposition methods. In the flapping foil experiment, two upstream NACA 0025 foils perform high-frequency synchronized motion and generate unsteady flow conditions for a downstream larger stationary foil. Fairly good agreement was obtained between unsteady experimental data and numerical results from two different moving boundary procedures. Incompressible Navier-Stokes code (INS3D) has been extended for heat transfer applications. The temperature equation was written for both forced and natural convection phenomena. Flow in a square duct case was used for the validation of the code in both natural and forced convection. Author

DIRECT NUMERICAL SIMULATION OF TRANSITIONAL AND TURBULENT FLOW OVER A HEATED FLAT PLATE USING FINITE-DIFFERENCE SCHEMES Final Report, Aug. 1993 - Jan. 1995
Nateri K. Madavan Jan. 1995 30 p Original contains color illustrations
(Contract NCC2-755)
(NASA-CR-197753; NAS 1.26:197753; MCAT-95-16) Avail: CASI HC A03/MF A01; 2 functional color pages

This report deals with the direct numerical simulation of transitional and turbulent flow at low Mach numbers using high-order-accurate finite-difference techniques. A computation of transition to turbulence of the spatially-evolving boundary layer on a heated flat plate in the presence of relatively high freestream turbulence was performed. The geometry and flow conditions were chosen to match earlier experiments. The development of the momentum and thermal boundary layers was documented. Velocity and temperature profiles, as well as distributions of skin friction, surface heat transfer rate, Reynolds shear stress, and turbulent heat flux, were shown to compare well with experiment. The results indicate that the essential features of the transition process have been captured. The numerical method used here can be applied to complex geometries in a straightforward manner. THE STABILITY OF THE FLOW IN A LAMINAR SEPARATION BUBBLE Thesis
Tai Ran Niew Sep. 1993 204 p Sponsored by St. John's College and Rolls Royce plc.
(ISSN 0309-7293)
(CUED/A-AERO/TR-22) Avail: CASI HC A10/MF A03

This dissertation reports a study into the underlying concepts used to analyze incompressible laminar separation bubbles. The suggestion that absolute instability could play a role in bubble flows was further developed, and was the focal point of this project. From a review of previous work and preliminary experiments on a backward faxing step, it was suggested that for some bubbles the reattachment region of the flow field could be absolutely unstable. A cornerstone of this view is that the completion of transition is not a prerequisite for the start of reattachment; and that a more fundamental mechanism involves significant interaction between the two processes. This concept was first tested by solving the eigenvalue problem of the Orr-Sommerfeld equation for a family of reverse flow profiles. The results indicated that with sufficient reverse flow, wall-bounded separated shear-layers that are similar to experimentally measured profiles can be absolutely unstable. This is consistent with the hypothesis outlined above. The numerical study also showed that for convectively unstable profiles, the predominant parameter that determines the spatial growth rate of instability waves is the distance of the separated shear layer from the wall. Furthermore, viscosity only has a weak effect on the stability characteristics of both absolutely and convectively unstable profiles at generic bubble Reynolds numbers. Experiments were then carried out on the flow behind a backward facing step using artificially excited instability waves, and the key issues in formulating a conceptually robust experimental method to test the above hypothesis was discussed. If the forcing was carried out with a non-acoustic source, it was shown that the use of impulse excitation could provide a rigorous procedure. Two qualitatively different transition mechanisms, 'wave' and 'spot' type, were also observed in these experiments. A new perspective of bubble behavior was then developed that considered the interaction of turbulent breakdown, reattachment and inducing of reverse flow. The concept of the absolutely unstable reattachment region is an integral part of this view, and the analysis was used to account for the different breakdown processes detected. Based on this alternative framework for analyzing bubble flows, a comprehensive list of fresh areas for future research was also suggested. Derived from text

ANALYSIS OF HYPERSONIC BOUNDARY LAYER SECOND MODE INSTABILITY OVER A 7 DEG CONE M.S. Thesis

Richard A. Dennery Dec. 1994 93 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289471; AFIT/GA/ENY/94D-20) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This paper presents the results of the analysis of Mach 8.0 flow over a seven degree half-angle cone. The purpose of this analysis was to develop techniques to examine boundary layer transition at hypersonic velocities. The specific objectives were to look for second mode instability waves characteristic of the transition process and to quantify the percentage of turbulent flow. Two sets of data were used in this analysis. The first set of data was taken at several axial positions at a freestream Reynolds number 4.265 million per meter. This data was used to develop the analysis techniques. The second set of data was taken at station 35 for Reynolds numbers of 3.28, 3.94, 4.92, and 6.56 million per meter. Spectral analysis was used to identify second mode disturbances, if they existed. The energy associated with the disturbances was then removed from the data signal to produce a new signal. The new signal was then evaluated using conditional sampling techniques. Additional methods used to assess turbulent intermittency were histogram analysis and examination of the power spectrum of the data signal. It was determined that removal of the disturbances from the raw data signal produced a cleaner signal. However, the new signals were not amenable to conditional sampling techniques. The histogram analysis proved to be inconclusive. Examination of the power spectrum showed that a laminar flow could be identified by the presence of a strong peak corresponding to the second mode disturbances, but could not be used to identify a flow as being turbulent by the absence of this peak. COMPRESSIBLE TURBULENCE MEASUREMENTS IN A SUPERSONIC BOUNDARY LAYER INCLUDING FAVORABLE PRESSURE GRADIENT EFFECTS M.S. Thesis

Raymond S. Miller 13 Dec. 1994 115 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289475; AFIT/GAE/ENY/94D-19) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The effect of a favorable pressure gradient on the turbulent flow structure in a Mach 2.9 boundary layer (Re/m approximately equal to 1.5 x 10(exp 7)) is investigated experimentally. Conventional flow and hot film measurements of turbulent fluctuation properties have been made upstream of and along an expansion ramp. Upstream measurements were taken in a zero pressure gradient boundary layer 44 cm from the nozzle throat in a 6.35 cm square test section. Measurements are obtained in the boundary layer, above the expansion ramp, 71.5 cm from the nozzle throat. Mean flow and turbulent flow characteristics are measured in all three dimensions. Comparisons are made between data obtained using single and multiple-overheat cross-wire anemometry as well as conventional mean flow probes. Conventional flow measurements were taken using a Pitot probe and a 10 degree cone static probe. Flow visualization was conducted via imaging techniques (Schlieren and shadowgraph photographs). Results suggest that compressibility effects, as seen through the density fluctuations in the Reynolds shear stress, are roughly 10% relative to the mean velocity and are large relative to the velocity fluctuations. This is also observed in the total Reynolds shear stress; compressibility accounts for 50-75% of the total shear. This is particularly true in the favorable pressure gradient region, where though the peak fluctuation intensities are diminished, the streamwise component of the mean flow is larger, hence the contribution of the compressibility term is significant in the Reynolds shear. COMPRESSIBLE TURBULENCE MEASUREMENTS IN A SUPERSONIC FLOW WITH ADVERSE PRESSURE GRADIENT M.S. Thesis

Jon W. Dotter Dec. 1994 121 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289477; AFIT/GAE/ENY/94D-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Mean flow and compressible turbulence measurements have been obtained upstream and in the vicinity of a compression ramp in Mach 3 flow. Compressible turbulence models have met with little success in the accurate prediction of high-speed flows involving complicated shock boundary interactions and adverse pressure gradients because of a crucial lack of experimental data. Data were collected using conventional Pitot and cone static probes, single overheat cross-wire anemometry, multiple overheat cross-wire anemometry, and flow visualization techniques. Direct measurements of the total Reynolds shear stress were obtained using a turbulence transformation. Results indicate that compressibility effects, as evidenced by the density fluctuations, are large relative to the velocity fluctuations and should be accounted for rigorously in new turbulence models. UNSTEADY BASE PRESSURE MEASUREMENTS IN THE NEAR WAKE OF A CYLINDER WITH IMPOSED THREE-DIMENSIONAL DISTURBANCES

J. P. Borg and A. A. Szewczyk 1995 2 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-4083)
(AD-A289498) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The effects of geometrically imposed three-dimensional disturbances that were introduced by a spanwise-periodic trailing-edge splitter plate on the instantaneous base pressure of a circular cylinder were investigated. Measurements indicate a direct coupling to the shedding frequency between the stagnation-line and base-pressure signals. A low frequency component in the base pressure power spectra was found and was directly related to the irregular shedding observed in the wake. DTIC

ADDRESSING TENSION INSTABILITY IN SPH METHODS Interim Report

C. T. Dyka and R. P. Ingel 30 Dec. 1994 23 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289531; NRL/MR/6384-94-7641) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Smoothed particle hydrodynamics (SPH) has the potential to be an important method for structural analysis. However, the SPH method is currently plagued by tension instability. A new unconventional approach is introduced, in which the stresses are calculated at points other than the SPH nodes, to address this difficulty. This algorithm is implemented into a one dimensional (1D) program called SPH1D. In addition, objective stress rate calculations are discussed and specialized to 1D applications. The results from applying the unconventional approach to a simple bar are very encouraging. The bar holds together in tension and compares quite well to a finite element analysis. DTIC

CONSTRUCTION OF ARBITRARY ORDER SCHEMES FOR MANY DIMENSIONAL WAVE EQUATION

J. Tuomela Sep. 1994 34 p
(PB95-184818; RR-A336) Avail: CASI HC A03/MF A01

The authors show that it is possible to construct arbitrary order stable schemes for the homogeneous and heterogeneous wave equation in any dimension. The construction is elementary and uses formal power series techniques. We shall also calculate exact stability limits in various cases, and apparently this limit depends only on the dimension of the space. NTIS

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF RELATIVE PHYSICAL ORIENTATION BETWEEN EVAPORATOR AND CONDENSER FOR A LOOP HEAT PIPE M.S. Thesis
Brad R. Thompson Dec. 1994 83 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289248; AFIT/GA/ENY/94D-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research examined the effects on performance of varying angular orientation and height differences between evaporator and condenser for a loop heat pipe. Performance was defined as the difference in temperature between evaporator and condenser (DELTA T). The pipe was evaluated at varying input power (Qin) for: varying evaporator and condenser angles, different coolant temperatures, and varying relative height differences. All analysis included only steady state operation. The performance was influenced by condenser angles, with an optimal condenser angle for best performance being +45 degrees from horizontal. Additionally, the evaporator angles were found to influence performance only at low Qin and low coolant temperatures. For high Qin' performance was independent of evaporator angle. For small Qin the DELTA T increased (poorer performance) with decreasing coolant temperature. However, for high Qin the DELTA T was independent of coolant temperature. For small Qin the DELTA T increased with increasing heights of evaporator over condenser. However, for high Qin the DELTA T was independent of the height difference. Additionally, pipe operation was sensitive to the rate of decrease of Qin. Finally, an unexplained anomaly shows the pipe to operate at two different DELTA T values for a given heat input. DTIC

FLOW VISUALIZATION OF A TURBULENT SHEAR FLOW USING AN OPTICAL WAVEFRONT SENSOR M.S. Thesis
Daniel W. Jewell Dec. 1994 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289208; AFIT/GEO/ENG/94D-04) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The research reported here investigated the use of a shearing interferometer (SI) wavefront sensor to determine the effects of shear-layer turbulence on an optical wavefront. A collimated helium-neon laser beam was propagated through a plane shear-layer produced by mixing helium and nitrogen at different velocities. Since the gases have different indices of refraction, the optical wavefront was distorted by different amounts by each gas. The SI measured the wavefront slope across the sampled area of the wavefront. The shear-layer was viewed from two orthogonal directions. This document contains shadow graphs, interference patterns imaged by each of the SI's six cameras, interferograms containing fringes with separation proportional to the wavefront slope, and phase maps showing the shape of the perturbed optical wavefronts. The side view showed an area of steep slope along the mixing area of the two gases. The slope gradually changed as the distance from the mixing layer region increased. For the top view, the peaks and valleys grew as they propagated away from the shear-layer turbulence generator. The results also indicated that the interference patterns recorded by the SI cameras provide a simple way to visualize turbulence in a manner that provides phase information about the wavefront. BASIC STUDIES IN TURBULENT SHEAR FLOWS Summary Report, Fiscal Year 1994
Fazle Hussain 1994 33 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1361)
(AD-A289145) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The goal of this research is to understand the underlying physics of turbulence phenomena through coherent structures (CS). The aim is not only to understand the flow physics but also to devise methods for turbulence prediction and control. Our approach utilizes experiment, numerics, and theory to understand both CS dynamics and structure. CS are studied in two ways: (1) long-time, global dynamics using experimental data and dynamical systems theory and (2) crucial, localized CS interactions understood via vorticity dynamics. Below, we have summarized results in several key areas: (1) global dynamics in a forced plane mixing layer (2) ODE models for spatially developing free shear flows, (3) core dynamics and transition in a plane mixing layer, (4) vorticity and helicity statistics in a circular jet, (5) new approaches to identifying sources of jet noise, and (6) the kinematic separation of homogeneous mixtures. (AD-A289147) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report summarizes a four year program on the development of high efficiency nonlinear optical materials. Major achievements were the development of effective top-seeded solution growth techniques for beta-barium borate (BBO) and lithium triborate (LBO). BBO crystals were also grown for the first time in the US by the direct melt growth technique, a metastable method that leads to significantly higher growth rates than the commercial solution-growth technique. High quality crystals were made available for optical property determinations and nonlinear optical device development at government and commercial laboratories. Additional accomplishments involved development of an optimum heat-treatment technology for eliminating optical scattering centers from as-grown crystals of silver gallium selenide. Cooperative programs were carried out with NRL to quantify the effects of intrinsic and extrinsic defects on residual absorption. It was discovered that silver gallium selenide and silver gallium sulfide crystals grown from silver-rich solutions are free of anomolous absorption in the 2 micron waveband which is currently the major problem limiting generation of high intensity, tunable 3-5 micron radiation by OPO methods using these materials. A new nonlinear optical material, (La,Gd)Sc3(BO3)4 has been identified for future study. DTIC

Research investigations involving the fundamental understanding and applications of nonlinear wave motion and related studies of inverse scattering and numerical computation have been carried out and a number of significant results have been obtained. A class of nonlinear wave equations which can be solved by the inverse scattering transform (IST) have been studied, including the Kadaomtsev-Petviashvili (KP) equation, the Davey-Stewartson equation, and the 2+1 Toda system. The solutions obtained by IST correspond to the Cauchy initial value problem with decaying initial data. We have also solved two important systems via the IST method: a 'Volterra' system in 2+1 dimensions and a new one dimensional nonlinear equation which we refer to as the Toda differential-delay equation. Research in computational chaos in moderate to long time numerical simulations continues. CASI

Research investigations on the interaction of surface waves, wind, and currents in stratified ocean layers have been carried out. The research program involves the development of appropriate models for general physical situations (e.g., systems of coupled nonlinear partial differential equations) as well as the analysis of these models for certain specific problems such as Langmuir circulations and double-diffusive convection. During the period of the report, six papers were published and two papers were accepted for publication. Some of the results obtained and the methods used in these papers are outlined in this report. UNSTRUCTURED MESH GENERATION AND ADAPTIVITY Final Report
D. J. Mavriplis Apr. 1995 48 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-195069; NAS 1.26:195069; ICASE-95-26) Avail: CASI HC A03/MF A01

An overview of current unstructured mesh generation and adaptivity techniques is given. Basic building blocks taken from the field of computational geometry are first described. Various practical mesh generation techniques based on these algorithms are then constructed and illustrated with examples. Issues of adaptive meshing and stretched mesh generation for anisotropic problems are treated in subsequent sections. The presentation is organized in an education manner, for readers familiar with computational fluid dynamics, wishing to learn more about current unstructured mesh techniques. Author

ON THE NONLINEAR STABILITY OF THE UNSTEADY, VISCOUS FLOW OF AN INCOMPRESSIBLE FLUID IN A CURVED PIPE Final Report
Trudi A. Shortis (Manchester Univ., England.) and Philip Hall (Manchester Univ., England.) Apr. 1995 24 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-195065; NAS 1.26:195065; ICASE-95-23) Avail: CASI HC A03/MF A01

The stability of the flow of an incompressible, viscous fluid through a pipe of circular cross-section curved about a central axis is investigated in a weakly nonlinear regime. A sinusoidal pressure gradient with zero mean is imposed, acting along the pipe. A WKBJ perturbation solution is constructed, taking into account the need for an inner solution in the vicinity of the outer bend, which is obtained by identifying the saddle point of the Taylor number in the complex plane of the cross-sectional angle co-ordinate. The equation governing the nonlinear evolution of the leading order vortex amplitude is thus determined. The stability analysis of this flow to periodic disturbances leads to a partial differential system dependent on three variables, and since the differential operators in this system are periodic in time, Floquet theory may be applied to reduce this system to a coupled infinite system of ordinary differential equations, together with homogeneous uncoupled boundary conditions. The eigenvalues of this system are calculated numerically to predict a critical Taylor number consistent with the analysis of Papageorgiou. A discussion of how nonlinear effects alter the linear stability analysis is also given, and the nature of the instability determined. Author

THE EFFECTS OF TRANSVERSE VIBRATION ON THE PERFORMANCE OF AN AXIAL GROOVE WICK HEAT PIPE M.S. Thesis
Kenneth A. Carpenter Dec. 1994 110 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289349; AFIT/GA/ENY/94D-5) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An experimental investigation was performed to determine the effects of transverse vibrations on the performance of an ammonia/aluminum axial groove wick heat pipe. Theoretical calculations predicted a performance degradation due to the working fluid being shaken out of the upper capillary grooves. A benchtop shaker was used to apply transverse, sinusoidal vibrations of 30, 35, and 40 Hertz, corresponding to peak acceleration amplitudes of 1.84g, 2.50g, and 3.27g, respectively. Maximum heat throughput, Q(sub max), of the vibrating heat pipe was measured. A comparison of these values and static Q(sub max) values indicated a degradation in heat pipe performance. A mean performance deterioration of 27.6 Watts was measured for the 1.84g case, an average degradation of 12.9 percent from static heat pipe performance. At 2.50g peak acceleration the degradation rose to 37.3 watts, an average decrease of 14.8 percent from static performance. An average deterioration in performance of 28.1 percent was recorded for the 3.27g case. This amounted to a mean performance degradation of 69.3 watts. The results of this investigation revealed that transverse, sinusoidal vibrations have a detrimental impact on the performance of an ammonia/axial groove wick heat pipe. Further, the performance degradation increases with increasing vibrational peak acceleration amplitude. DTIC

THE CALCULATION OF THE MASS MOMENT OF INERTIA OF A FLUID IN A ROTATING RECTANGULAR TANK Final Report
[1977] 46 p

(Grant NAG2-510)
(NASA-CR-197777; NAS 1.26:197777) Avail: CASI HC A03/MF A01

This analysis calculated the mass moment of inertia of a nonviscous fluid in a slowly rotating rectangular tank. Given the dimensions of the tank in the x, y, and z coordinates, the axis of rotation, the percentage of the tank occupied by the fluid, and angle of rotation, an algorithm was written that could calculate the mass moment of inertia of the fluid. While not included in this paper, the change in the mass moment of inertia of the fluid could then be used to calculate the force exerted by the fluid on the container wall. Derived from text

AN OUTFLOW BOUNDARY CONDITION FOR AEROACOUSTIC COMPUTATIONS
M. Ehtesham Hayder and Thomas Hagstrom (New Mexico Univ., Albuquerque, NM.) May 1995 8 p Presented at the ASME Fluids Engineering Division Summer Meeting, Hilton Head Island, SC, 13-18 Aug. 1995; cosponsored by ASME, JSME, and EALA
(Contract NCC3-370; RTOP 505-90-5K)
(NASA-TM-106930; E-9651; NAS 1.15:106930; ICOMP-95-10) Avail: CASI HC A02/MF A01

A formulation of boundary condition for flows with small disturbances is presented. The authors test their methodology in an axisymmetric jet flow calculation, using both the Navier-Stokes and Euler equations. Solutions in the far field are assumed to be oscillatory. If the oscillatory disturbances are small, the growth of the solution variables can be predicted by linear theory. Eigenfunctions of the linear theory are used explicitly in the formulation of the boundary conditions. This guarantees correct solutions at the boundary in the limit where the predictions of linear theory are valid. Author

ACOUSTIC FIELD IN UNSTEADY MOVING MEDIA Final Report
F. Bauer (New York Univ., New York, NY.), L. Maestrello, and L. Ting (New York Univ., New York, NY.) May 1995 48 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198162; NAS 1.26:198162; ICASE-95-39) Avail: CASI HC A03/MF A01

In the interaction of an acoustic field with a moving airframe the authors encounter a canonical initial value problem for an acoustic field induced by an unsteady source distribution, q(t,x) with q equivalent to 0 for t less than or equal to 0, in a medium moving with a uniform unsteady velocity U(t)i in the coordinate system x fixed on the airframe. Signals issued from a source point S in the domain of dependence D of an observation point P at time t will arrive at point P more than once corresponding to different retarded times, Tau in the interval (0, t). The number of arrivals is called the multiplicity of the point S. The multiplicity equals 1 if the velocity U remains subsonic and can be greater when U becomes supersonic. For an unsteady uniform flow U(t)i, rules are formulated for defining the smallest number of I subdomains V(sub i) of D with the union of V(sub i) equal to D. Each subdomain has multiplicity 1 and a formula for the corresponding retarded time. The number of subdomains V(sub i) with nonempty intersection is the multiplicity m of the intersection. The multiplicity is at most I. Examples demonstrating these rules are presented for media at accelerating and/or decelerating supersonic speed. Author

(AD-A289262) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The objective of the workshop on Flow Control was to bring together the ever growing community of mathematicians who are addressing these problems by sophisticated numerical and analytical techniques. They used a variety of mathematical tools and the workshop provided them an opportunity for an exchange and comparison of the different approaches. The second objective met by the workshop was to identify some of the important problems, from the point of view of applications, that need to be addressed by mathematicians, including specific flow control and optimization problems of interest to engineers. APPLICATION OF CFD TO THE ANALYSIS AND DESIGN OF HIGH-SPEED INLETS Final Report, 1 Jan. - 31 Dec. 1994
William C. Rose 25 May 1995 75 p Original contains color illustrations
(Contract NCC2-507)
(NASA-CR-198574; NAS 1.26:198574) Avail: CASI HC A04/MF A01; 15 functional color pages

Over the past seven years, efforts under the present Grant have been aimed at being able to apply modern Computational Fluid Dynamics to the design of high-speed engine inlets. In this report, a review of previous design capabilities (prior to the advent of functioning CFD) was presented and the example of the NASA 'Mach 5 inlet' design was given as the premier example of the historical approach to inlet design. The philosophy used in the Mach 5 inlet design was carried forward in the present study, in which CFD was used to design a new Mach 10 inlet. An example of an inlet redesign was also shown. These latter efforts were carried out using today's state-of-the-art, full computational fluid dynamics codes applied in an iterative man-in-the-loop technique. The potential usefulness of an automated machine design capability using an optimizer code was also discussed. Derived from text

NONLINEAR STABILITY OF NON-STATIONARY CROSS-FLOW VORTICES IN COMPRESSIBLE BOUNDARY LAYERS
J. S. B. Gajjar Cleveland, OH NASA May 1995 34 p
(Contract NCC3-370; RTOP 505-90-5K)
(NASA-CR-189184; E-9608; NAS 1.26:189184; ICOMP-95-7) Avail: CASI HC A03/MF A01

The nonlinear evolution of long wavelength non-stationary cross-flow vortices in a compressible boundary layer is investigated and the work extends that of Gajjar (1994) to flows involving multiple critical layers. The basic flow profile considered in this paper is that appropriate for a fully three-dimensional boundary layer with O(1) Mach number and with wall heating or cooling. The governing equations for the evolution of the cross-flow vortex are obtained and some special cases are discussed. One special case includes linear theory where exact analytic expressions for the growth rate of the vortices are obtained. Another special case is a generalization of the Bassom & Gajjar (1988) results for neutral waves to compressible flows. The viscous correction to the growth rate is derived and it is shown how the unsteady nonlinear critical layer structure merges with that for a Haberman type of viscous critical layer. Author

SPECTRAL METHODS ON ARBITRARY GRIDS Final Report
Mark H. Carpenter and David Gottlieb (Brown Univ., Providence, RI.) May 1995 30 p
(Contracts NAS1-19480; RTOP 505-90-52-01; AF-AFOSR-0090-93; N00014-91-J-4016; NSF DMS-92-11820)
(NASA-CR-198158; NAS 1.26:198158; ICASE-95-37) Avail: CASI HC A03/MF A01

Stable and spectrally accurate numerical methods are constructed on arbitrary grids for partial differential equations. These new methods are equivalent to conventional spectral methods but do not rely on specific grid distributions. Specifically, we show how to implement Legendre Galerkin, Legendre collocation, and Laguerre Galerkin methodology on arbitrary grids. Author

COMPUTER PROGRAM BL2D FOR SOLVING TWO-DIMENSIONAL AND AXISYMMETRIC BOUNDARY LAYERS
Venkit Iyer NASA May 1995 98 p
(Contract NAS1-19672; RTOP 537-03-23-03)
(NASA-CR-4668; NAS 1.26:4668) Avail: CASI HC A05/MF A02

This report presents the formulation, validation, and user's manual for the computer program BL2D. The program is a fourth-order-accurate solution scheme for solving two-dimensional or axisymmetric boundary layers in speed regimes that range from low subsonic to hypersonic Mach numbers. A basic implementation of the transition zone and turbulence modeling is also included. The code is a result of many improvements made to the program VGBLP, which is described in NASA TM-83207 (February 1982), and can effectively supersede it. The code BL2D is designed to be modular, user-friendly, and portable to any machine with a standard fortran77 compiler. The report contains the new formulation adopted and the details of its implementation. Five validation cases are presented. A detailed user's manual with the input format description and instructions for running the code is included. Adequate information is presented in the report to enable the user to modify or customize the code for specific applications. Author

THE SIXTH ANNUAL THERMAL AND FLUIDS ANALYSIS WORKSHOP

Jan. 1995 314 p Workshop held in Brook Park, OH, 15-19 Aug. 1994 rk, OH, 15-19 Aug. 1994

(NASA-CP-10161; E-9214; NAS 1.55:10161) Avail: CASI HC A14/MF A03

The Sixth Annual Thermal and Fluids Analysis Workshop consisted of classes, vendor demonstrations, and paper sessions. The classes and vendor demonstrations provided participants with the information on widely used tools for thermal and fluids analysis. The paper sessions provided a forum for the exchange of information and ideas among thermal and fluids analysis. Paper topics included advances an uses of established thermal and fluids computer codes (such as SINDA and TRASYS) as well as unique modeling techniques and applications. For individual titles, see N95-27346 through N95-27365.

EXTENSIONAL FLOW CONVECTING A REACTANT UNDERGOING A FIRST ORDER HOMOGENEOUS REACTION AND DIFFUSIONAL MASS TRANSFER FROM A SPHERE AT LOW TO INTERMEDIATE PECLET AND DAMKOHLER NUMBERS

N. Y. Shah and X. B. Reed, Jr. *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 1-23 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

Forced convective diffusion-reaction is considered for viscous axisymmetric extensional convecting velocity in the neighborhood of a sphere. For Peclet numbers in the range 0.1 less than or equal to Pe less than or equal to 500 and for Damkohler numbers increasing with increasing Pe but in the overall range 0.02 less than or equal to Da less than or equal to 10, average and local Sherwood numbers have been computed. By introducing the eigenfunction expansion c(r, Theta) = Sum of c(n)(r)P(n)(cos Theta) into the forced convective diffusion equation for the concentration of a chemical species undergoing a first order homogeneous reaction and by using properties of the Legendre functions Pn(cos Theta), the variable coefficient PDE can be reduced to a system of N + 1 second order ODEs for the radial functions c(sub n)(r), n = 0, 1, 2,..., N. The adaptive grid algorithm of Pereyra and Lentini can be used to solve the corresponding 2(N + 1) first order differential equations as a two-point boundary value problem on 1 less than or equal to r less than or equal to r(sub infinity). Convergence of the expansion for a specific value of N can thus be established and provides 'spectral' behavior as well as the full concentration field c(r, Theta). Author

COMPUTATION OF THREE-DIMENSIONAL MIXED CONVECTIVE BOUNDARY LAYER FLOW

Prashandt Gadepalli and Muhammad M. Rahman *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 25-36 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The paper presents the numerical solution of heat and mass transfer during cross-flow (orthogonal) mixed convection. In this class of flow, a buoyancy-driven transport in the vertical direction and a forced convective flow in the horizontal direction results in a three-dimensional boundary layer structure adjacent to the plate. The rates of heat and mass transfer are determined by a combined influence of the two transport processes. The equations for the conservation of mass, momentum, energy, and species concentration were solved along with appropriate boundary conditions to determine the distributions of velocity components, temperature, and concentration across the thickness of the boundary layer at different locations on the plate. Results were expressed in dimensionless form using Reynolds number, Richardson number for heat transfer, Richardson number for mass transfer, Prandtl number, and Schmidt number as parameters. It was found that the transport is dominated by buoyancy at smaller vertical locations and at larger distances away from the forced convection leading edge. Effects of forced convection appeared to be very strong at smaller horizontal distances from the leading edge. The cross stream forced convection enhanced the rate of heat and mass transfer by a very significant amount. Author

ANALYSIS OF GAS ABSORPTION TO A THIN LIQUID FILM IN THE PRESENCE OF A ZERO-ORDER CHEMICAL REACTION

S. Rajagopalan and M. M. Rahman *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 37-52 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The paper presents a detailed theoretical analysis of the process of gas absorption to a thin liquid film adjacent to a horizontal rotating disk. The film is formed by the impingement of a controlled liquid jet at the center of the disk and subsequent radial spreading of liquid along the disk. The chemical reaction between the gas and the liquid film can be expressed as a zero-order homogeneous reaction. The process was modeled by establishing equations for the conservation of mass, momentum, and species concentration and solving them analytically. A scaling analysis was used to determine dominant transport processes. Appropriate boundary conditions were used to solve these equations to develop expressions for the local concentration of gas across the thickness of the film and distributions of film height, bulk concentration, and Sherwood number along the radius of the disk. The partial differential equation for species concentration was solved using the separation of variables technique along with the Duhamel's theorem and the final analytical solution was expressed using confluent hypergeometric functions. Tables for eigenvalues and eigenfunctions are presented for a number of reaction rate constants. A parametric study was performed using Reynolds number, Ekman number, and dimensionless reaction rate as parameters. At all radial locations, Sherwood number increased with Reynolds number (flow rate) as well as Ekman number (rate of rotation). The enhancement of mass transfer due to chemical reaction was found to be small when compared to the case of no reaction (pure absorption), but the enhancement factor was very significant when compared to pure absorption in a stagnant liquid film. The zero-order reaction processes considered in the present investigation included the absorption of oxygen in aqueous alkaline solutions of sodiumdithionite and rhodium complex catalyzed carbonylation of methanol. Present analytical results were compared to previous theoretical results for limiting conditions, and were found to have very good agreement. Author

FEATURES AND APPLICATIONS OF THE GROOVE ANALYSIS PROGRAM (GAP)

Jentung Ku, Tu M. Nguyen (OAO Corp., Greenbelt, MD.), and Patrick J. Brennan (OAO Corp., Greenbelt, MD.) *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 53-68 (For primary document see N95-27345 09-34)
Avail: CASI HC A03/MF A03

An IBM Personal Computer (PC) version of the Groove Analysis program (GAP) was developed to predict the steady state heat transport capability of an axially grooved heat pipe for a specified groove geometry and working fluid. In the model, the capillary limit is determined by the numerical solution of the differential equation for momentum conservation with the appropriate boundary conditions. This governing equation accounts for the hydrodynamic losses due to friction in liquid and vapor flows and due to liquid/vapor shear interaction. Back-pumping in both 0-g and 1-g is accounted for in the boundary condition at the condenser end. Slug formation in 0-g and puddle flow in 1-g are also considered in the model. At the user's discretion, the code will perform the analysis for various fluid inventories (undercharge, nominal charge, overcharge, or a fixed fluid charge) and heat pipe elevations. GAP will also calculate the minimum required heat pipe wall thickness for pressure containment at design temperatures that are greater than or lower than the critical temperature of the working fluid. This paper discusses the theory behind the development of the GAP model. It also presents the many useful and powerful capabilities of the model. Furthermore, a correlation of flight test performance data and the predictions using GAP are presented and discussed. Author

VALIDATION OF THE SINDA/FLUINT CODE USING SEVERAL ANALYTICAL SOLUTIONS

John R. Keller *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 69-84 (For primary document see N95-27345 09-34)
Avail: CASI HC A03/MF A03

The Systems Improved Numerical Differencing Analyzer and Fluid Integrator (SINDA/FLUINT) code has often been used to determine the transient and steady-state response of various thermal and fluid flow networks. While this code is an often used design and analysis tool, the validation of this program has been limited to a few simple studies. For the current study, the SINDA/FLUINT code was compared to four different analytical solutions. The thermal analyzer portion of the code (conduction and radiative heat transfer, SINDA portion) was first compared to two separate solutions. The first comparison examined a semi-infinite slab with a periodic surface temperature boundary condition. Next, a small, uniform temperature object (lumped capacitance) was allowed to radiate to a fixed temperature sink. The fluid portion of the code (FLUINT) was also compared to two different analytical solutions. The first study examined a tank filling process by an ideal gas in which there is both control volume work and heat transfer. The final comparison considered the flow in a pipe joining two infinite reservoirs of pressure. The results of all these studies showed that for the situations examined here, the SINDA/FLUINT code was able to match the results of the analytical solutions. Author

TRANSIENT STUDIES OF G-INDUCED CAPILLARY DRYOUT AND REWET

M. K. Reagan and W. J. Bowman *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 85-105 (For primary document see N95-27345 09-34)
Avail: CASI HC A03/MF A03

A transient, one-dimensional numerical code is developed to model the liquid motion in an axial groove with square cross section. Axial variation in liquid level, shear stress and heat transfer between the groove wall and the liquid, evaporation and transient body forces are accounted for in the model. Dryout and rewet of the groove are allowed; the front location is determined numerically using conservation of mass and linear extrapolation. Several numerical test results are presented and discussed. Author

ANALYSIS OF DEVELOPING LAMINAR FLOWS IN CIRCULAR PIPES USING A HIGHER-ORDER FINITE-DIFFERENCE TECHNIQUE

Herbert J. Gladden, Ching L. Ko (Oakland Univ., Rochester, MI.), and Douglas E. Boddy (Oakland Univ., Rochester, MI.) *In its* The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 107-114 (For primary document see N95-27345 09-34)
Avail: CASI HC A02/MF A03

A higher-order finite-difference technique is developed to calculate the developing-flow field of steady incompressible laminar flows in the entrance regions of circular pipes. Navier-Stokes equations governing the motion of such a flow field are solved by using this new finite-difference scheme. This new technique can increase the accuracy of the finite-difference approximation, while also providing the option of using unevenly spaced clustered nodes for computation such that relatively fine grids can be adopted for regions with large velocity gradients. The velocity profile at the entrance of the pipe is assumed to be uniform for the computation. The velocity distribution and the surface pressure drop of the developing flow then are calculated and compared to existing experimental measurements reported in the literature. Computational results obtained are found to be in good agreement with existing experimental correlations and therefore, the reliability of the new technique has been successfully tested. Author

A CASE STUDY OF VIEW-FACTOR RECTIFICATION PROCEDURES FOR DIFFUSE-GRAY RADIATION ENCLOSURE COMPUTATIONS

Robert P. Taylor and Rogelio Luck *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 115-131 (For primary document see N95-27345 09-34)
Avail: CASI HC A03/MF A03

The view factors which are used in diffuse-gray radiation enclosure calculations are often computed by approximate numerical integrations. These approximately calculated view factors will usually not satisfy the important physical constraints of reciprocity and closure. In this paper several view-factor rectification algorithms are reviewed and a rectification algorithm based on a least-squares numerical filtering scheme is proposed with both weighted and unweighted classes. A Monte-Carlo investigation is undertaken to study the propagation of view-factor and surface-area uncertainties into the heat transfer results of the diffuse-gray enclosure calculations. It is found that the weighted least-squares algorithm is vastly superior to the other rectification schemes for the reduction of the heat-flux sensitivities to view-factor uncertainties. In a sample problem, which has proven to be very sensitive to uncertainties in view factor, the heat transfer calculations with weighted least-squares rectified view factors are very good with an original view-factor matrix computed to only one-digit accuracy. All of the algorithms had roughly equivalent effects on the reduction in sensitivity to area uncertainty in this case study. Author

CAE FOR THERMAL MANAGEMENT OF AEROSPACE ELECTRONIC BOARDS USING THE BETASOFT PROGRAM c33

Kimberly Bobish *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 133-140 (For primary document see N95-27345 09-34)
Avail: CASI HC A02/MF A03

Aerospace electronic boards require special attention to thermal management due to constraints such as their need to be light, small, and maintain high power densities. Also, cooling is mainly through conductive and radiative modes with minor or negligible convective cooling. Due to these particular requirements, thermal design has become an integrated part of the electronic design process in order to avoid expensive repeat prototyping and to ensure high reliability. To achieve high speed simulations, the BETAsoft code uses semi-empirical formulations and an advanced finite difference scheme that incorporates local adaptive grids. Detailed conduction, convection and radiation heat transfer is considered. Various benchmark verifications of the software simulation compared to infrared images typically prove to be within 10% of each other. The thermal analysis of a sample avionic card in a natural convection environment is shown. Then, the individual effects of attaching metal screws to the casing, increasing radiative emissivities of the casing, increasing the conductance of the wedge lock, adding an aluminum core to the board, adding metal strips in board layers, inserting conduction pads under components, and adding heat sinks to components are demonstrated. RTE: A COMPUTER CODE FOR ROCKET THERMAL EVALUATION

c20

Mohammad H. N. Naraghi *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 141-162 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The numerical model for a rocket thermal analysis code (RTE) is discussed. RTE is a comprehensive thermal analysis code for thermal analysis of regeneratively cooled rocket engines. The input to the code consists of the composition of fuel/oxidant mixture and flow rates, chamber pressure, coolant temperature and pressure. dimensions of the engine, materials and the number of nodes in different parts of the engine. The code allows for temperature variation in axial, radial and circumferential directions. By implementing an iterative scheme, it provides nodal temperature distribution, rates of heat transfer, hot gas and coolant thermal and transport properties. The fuel/oxidant mixture ratio can be varied along the thrust chamber. This feature allows the user to incorporate a non-equilibrium model or an energy release model for the hot-gas-side. The user has the option of bypassing the hot-gas-side calculations and directly inputting the gas-side fluxes. This feature is used to link RTE to a boundary layer module for the hot-gas-side heat flux calculations. Author

EFFECT OF TURBULENCE MODELS ON CRITICALITY CONDITIONS IN SWIRLING FLOWS

Thomas B. Gatski and Robert E. Spall (University of South Alabama, Mobile, AL.) *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 163-173 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The critical state of vortex cores downstream of vortex breakdown has been studied. Base vortical flows were computed using the Reynolds-averaged, axisymmetric Navier-Stokes equations. Standard K - epsilon, RNG and second-order Reynolds stress models were employed. Results indicate that the return to supercriticality is highly dependent on the turbulence model. The K - epsilon model predicted a rapid return of the vortex to supercritical conditions, the location of which showed little sensitivity to changes in the swirl ratio. The Reynolds stress model predicted that the vortex remains subcritical to the end of the domain for each of the swirl ratios employed, and provided results in qualitative agreement with experimental work. The RNG model produced intermediate results, with a downstream movement in the critical location with increasing swirl. Calculations for which area reductions were introduced at the exit in a subcritical flow were also performed using the Reynolds stress model. The structure of the resulting recirculation zone was altered significantly. However, when area reductions were employed within supercritical flows as predicted using the two-equation models, no significant influence on the recirculation zone was noted. Author

NUMERICAL SOLUTION OF FLUID FLOW AND HEAT TRANFER PROBLEMS WITH SURFACE RADIATION

S. Ahuja and K. Bhatia *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 175-188 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

This paper presents a numerical scheme, based on the finite element method, to solve strongly coupled fluid flow and heat transfer problems. The surface radiation effect for gray, diffuse and isothermal surfaces is considered. A procedure for obtaining the view factors between the radiating surfaces is discussed. The overall solution strategy is verified by comparing the available results with those obtained using this approach. An analysis of a thermosyphon is undertaken and the effect of considering the surface radiation is clearly explained. Author

SINGLE-DROP REACTIVE EXTRACTION/EXTRACTIVE REACTION WITH FORCED CONVECTIVE DIFFUSION AND INTERPHASE MASS TRANSFER

Leonid S. Kleinman and X. B. Reed, Jr. *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 189-213 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

An algorithm has been developed for the forced convective diffusion-reaction problem for convection inside and outside a droplet by a recirculating flow field hydrodynamically coupled at the droplet interface with an external flow field that at infinity becomes a uniform streaming flow. The concentration field inside the droplet is likewise coupled with that outside by boundary conditions at the interface. A chemical reaction can take place either inside or outside the droplet or reactions can take place in both phases. The algorithm has been implemented and results are shown here for the case of no reaction and for the case of an external first order reaction, both for unsteady behavior. For pure interphase mass transfer, concentration isocontours, local and average Sherwood numbers, and average droplet concentrations have been obtained as a function of the physical properties and external flow field. For mass transfer enhanced by an external reaction, in addition to the above forms of results, we present the enhancement factor, with the results now also depending upon the (dimensionless) rate of reaction. Author

A PROBABILISTIC MODEL OF A POROUS HEAT EXCHANGER

O. P. Agrawal and X. A. Lin *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 215-226 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

This paper presents a probabilistic one-dimensional finite element model for heat transfer processes in porous heat exchangers. The Galerkin approach is used to develop the finite element matrices. Some of the submatrices are asymmetric due to the presence of the flow term. The Neumann expansion is used to write the temperature distribution as a series of random variables, and the expectation operator is applied to obtain the mean and deviation statistics. To demonstrate the feasibility of the formulation, a one-dimensional model of heat transfer phenomenon in superfluid flow through a porous media is considered. Results of this formulation agree well with the Monte-Carlo simulations and the analytical solutions. Although the numerical experiments are confined to parametric random variables, a formulation is presented to account for the random spatial variations. Author

TRANSITIONAL FLOW IN THIN TUBES FOR SPACE STATION FREEDOM RADIATOR

Patrick Loney and Mounir Ibrahim (Cleveland State Univ., OH.) *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 227-232 (For primary document see N95-27345 09-34)

Avail: CASI HC A02/MF A03

A two dimensional finite volume method is used to predict the film coefficients in the transitional flow region (laminar or turbulent) for the radiator panel tubes. The code used to perform this analysis is CAST (Computer Aided Simulation of Turbulent Flows). The information gathered from this code is then used to augment a Sinda85 model that predicts overall performance of the radiator. A final comparison is drawn between the results generated with a Sinda85 model using the Sinda85 provided transition region heat transfer correlations and the Sinda85 model using the CAST generated data. A NAVIER-STOKES BOUNDARY ELEMENT SOLVER

D. R. Reddy, O. Lafe (OLTech Corp., Chesterland, OH.), and A. H-D. Cheng (Delaware Univ., Newark, DE.) *In its* The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 233-246 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

Using global interpolation functions (GIF's) boundary element solutions are obtained for two-dimensional laminar flows. Two schemes are proposed for handling the convective terms. The first treats convection as a forcing function, and converts the flow equations to pseudo-Poisson equations. In the second scheme, some convective effect is incorporated into the fundamental solution used in constructing the pertinent integral equations. The lid-driven cavity flow is selected as the benchmark problem. Author

TURBULANCE BOUNDARY CONDITIONS FOR SHEAR FLOW ANALYSIS, USING THE DTNS FLOW SOLVER

M. Mizukami *In its* The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 247-262 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The effects of different turbulence boundary conditions were examined for two classical flows: a turbulent plane free shear layer and a flat plate turbulent boundary layer with zero pressure gradient. The flow solver used was DTNS, an incompressible Reynolds averaged Navier-Stokes solver with k-epsilon turbulence modeling, developed at the U.S. Navy David Taylor Research Center. Six different combinations of turbulence boundary conditions at the inflow boundary were investigated: In case 1, 'exact' k and epsilon profiles were used; in case 2, the 'exact' k profile was used, and epsilon was extrapolated upstream; in case 3, both k and epsilon were extrapolated; in case 4, the turbulence intensity (I) was 1 percent, and the turbulent viscosity (mu(sub t)) was equal to the laminar viscosity; in case 5, the 'exact' k profile was used and mu(sub t) was equal to the laminar viscosity; in case 6, the I was 1 percent, and epsilon was extrapolated. Comparisons were made with experimental data, direct numerical simulation results, or theoretical predictions as applicable. Results obtained with DTNS showed that turbulence boundary conditions can have significant impacts on the solutions, especially for the free shear layer. Author

THERMAL NEUTRAL FORMAT BASED ON THE STEP TECHNOLOGY

P. Planas Almazan and J. L. LeGal (Centre National d'Etudes Spatiales, Toulouse, France.) *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 263-273 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The exchange of models is one of the most serious problems currently encountered in the practice of spacecraft thermal analysis. Essentially, the problem originates in the diversity of computing environments that are used across different sites, and the consequent proliferation of native tool formats. Furthermore, increasing pressure to reduce the development's life cycle time has originated a growing interest in the so-called spacecraft concurrent engineering. In this context, the realization of the interdependencies between different disciplines and the proper communication between them become critical issues. The use of a neutral format represents a step forward in addressing these problems. Such a means of communication is adopted by consensus. A neutral format is not directly tied to any specific tool and it is kept under stringent change control. Currently, most of the groups promoting exchange formats are contributing with their experience to STEP, the Standard for Exchange of Product Model Data, which is being developed under the auspices of the International Standards Organization (ISO 10303). This paper presents the different efforts made in Europe to provide the spacecraft thermal analysis community with a Thermal Neutral Format (TNF) based on STEP. Following an introduction with some background information, the paper presents the characteristics of the STEP standard. Later, the first efforts to produce a STEP Spacecraft Thermal Application Protocol are described. Finally, the paper presents the currently harmonized European activities that follow up and extend earlier work on the area. Author

THE BENARD PROBLEM: A COMPARISON OF FINITE DIFFERENCE AND SPECTRAL COLLOCATION EIGEN VALUE SOLUTIONS

J. Raymond Lee Skarda, Frances E. McCaughan (Case Western Reserve Univ., Cleveland, OH.), and Nessan Fitzmaurice (Case Western Reserve Univ., Cleveland, OH.) *In its* The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 275-290 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

The application of spectral methods, using a Chebyshev collocation scheme, to solve hydrodynamic stability problems is demonstrated on the Benard problem. Implementation of the Chebyshev collocation formulation is described. The performance of the spectral scheme is compared with that of a 2nd order finite difference scheme. An exact solution to the Marangoni-Benard problem is used to evaluate the performance of both schemes. The error of the spectral scheme is at least seven orders of magnitude smaller than finite difference error for a grid resolution of N = 15 (number of points used). The performance of the spectral formulation far exceeded the performance of the finite difference formulation for this problem. The spectral scheme required only slightly more effort to set up than the 2nd order finite difference scheme. This suggests that the spectral scheme may actually be faster to implement than higher order finite difference schemes. Author

SINGLE-DROP REACTIVE EXTRACTION/EXTRACTIVE REACTION WITH FORCED CONVECTIVE DIFFUSION AND INTERPHASE MASS TRANSFER

Leonid S. Kleinman and X. B. Red, Jr. *In* NASA. Lewis Research Center, The Sixth Annual Thermal and Fluids Analysis Workshop Jan. 1995 p 291-315 (For primary document see N95-27345 09-34)

Avail: CASI HC A03/MF A03

An algorithm has been developed for time-dependent forced convective diffusion-reaction having convection by a recirculating flow field within the drop that is hydrodynamically coupled at the interface with a convective external flow field that at infinity becomes a uniform free-streaming flow. The concentration field inside the droplet is likewise coupled with that outside by boundary conditions at the interface. A chemical reaction can take place either inside or outside the droplet, or reactions can take place in both phases. The algorithm has been implemented, and for comparison results are shown here for the case of no reaction in either phase and for the case of an external first order reaction, both for unsteady behavior. For pure interphase mass transfer, concentration isocontours, local and average Sherwood numbers, and average droplet concentrations have been obtained as a function of the physical properties and external flow field. For mass transfer enhanced by an external reaction, in addition to the above forms of results, we present the enhancement factor, with the results now also depending upon the (dimensionless) rate of reaction. COMPOSITE HEAT PIPE DEVELOPMENT STATUS: DEVELOPMENT OF LIGHTWEIGHT PROTOTYPE CARBON-CARBON HEAT PIPE WITH INTEGRAL FINS AND METAL FOIL LINER

Albert J. Juhasz and Richard D. Rovang (Rockwell International Corp., Canoga Park, CA.) May 1995 12 p Presented at the 9th International Heat Pipe Conference, Albuquerque, NM, 1-5 May 1995; sponsored by LANL

(RTOP 233-02-0B)
(NASA-TM-106909; E-9611; NAS 1.15:106909) Avail: CASI HC A03/MF A01

This report discusses development and proof-of-concept testing of a new lightweight carbon-carbon (C-C) space radiator heat pipe, carried out under the NASA Civil Space Technology Initiative (CSTI) High Capacity Power Program. The prototype heat pipe, equipped with a niobium-zirconium foil liner, was filled with potassium working fluid and tested for 11 hours, including startup from ambient temperature with the working fluid initially in the frozen state to near 700 K condenser temperature. Steady-state heat pipe input power during testing was facility limited to about 300 watts. Post test inspection showed the heat pipe to be in excellent condition after eight thermal cycles from ambient to steady-state operating temperature. Utilization of other liner materials and working fluids would greatly extend the spectrum of service temperatures for this technology, with potential applications ranging from small spacecraft heat rejection to aircraft and terrestrial uses. A NEW FINITE ELEMENT FORMULATION FOR INCOMPRESSIBLE FLOW
L. V. Curfman 1995 27 p
(Contract W-31-109-eng-38)
(DE95-007141; ANL/MCS/PP-80304) Avail: CASI HC A03/MF A01

A basic objective in computational fluid dynamics is the efficient solution of nonlinear systems of equations that arise in finite element modeling of convective-diffusive flow. The use of implicit Newton-like schemes to solve the coupled system of Navier-Stokes and continuity equations enables rapid convergence, although the well-known difficulty of indirect pressure linkage requires attention when forming the Jacobian matrices. Traditional approaches for overcoming this obstacle include reordering strategies, modification of diagonal terms, and changes of variables. In contrast, the author develops a primitive variable finite element formulation which employs an auxiliary pressure equation derived from the Navier-Stokes and continuity equations. This formulation extends the work of Rice and Schnipke, where a similar equation was developed in the context of a segregated solution method. Approximate Newton methods using the new finite element formulation are evaluated in terms of accuracy, convergence rate, and overall efficiency for flow problems with varying degrees of nonlinearity. THE USE OF WAVELET TRANSFORMS IN THE SOLUTION OF TWO-PHASE FLOW PROBLEMS
G. J. Moridis, M. Nikolaou (Texas A&M Univ., College Station, TX.), and Yong You (Texas A&M Univ., College Station, TX.) Oct. 1994 10 p Presented at the Symposium on Reservoir Simulation, San Antonio, TX, 12-15 Feb. 1995
(Contract DE-AC03-76SF-00098)
(DE95-004688; LBL-36328; CONF-950206-1) Avail: CASI HC A02/MF A01

We present the use of wavelets to solve the nonlinear partial differential equation (PDE) of two-phase flow in one dimension. The wavelet transforms allow a drastically different approach in the discretization of space. In contrast to the traditional trigonometric basis functions, wavelets approximate a function not by cancellation but by placement of wavelets at appropriate locations. When an abrupt change, such as a shock wave or a spike, occurs in a function, only local coefficients in a wavelet approximation will be affected. The unique feature of wavelets is their multi-resolution analysis (MRA) property, which allows seamless investigation at any spatial resolution. The use of wavelets is tested in the solution of the one-dimensional Buckley-Leverett problem against analytical solutions and solutions obtained from standard numerical models. Two classes of wavelet bases (Daubechies and Chui-Wang) and two methods (Galerkin and collocation) are investigated. We determine that the Chui-Wang wavelets and a collocation method provide the optimum wavelet solution for this type of problem. Increasing the resolution level improves the accuracy of the solution, but the order of the basis function seems to be far less important. Our results indicate that wavelet transforms are an effective and accurate method which does not suffer from oscillations or numerical smearing in the presence of steep fronts. DOE

The evolution of large amplitude Tollmien-Schlichting waves in a supersonic boundary layer is investigated. Disturbances which have their wavenumber and frequency slowly varying in time and space are described using a phase equation type of approach. Unlike the incompressible case we find that the initial bifurcation to a finite amplitude Tollmien-Schlichting wave is subcritical for most Mach numbers. In fact the bifurcation is only supercritical for a small range of Mach numbers and even then for only a finite range of wave propagation angles. The modulational instability of large amplitude wavetrains is considered and is shown to be governed by an equation similar to Burgers equation but with the viscous term replaced by a fractional derivative. A numerical investigation of the solution of this equation is described. It is shown that uniform wavetrains are unstable. Author

The visualization of fluid flows has become more challenging, as recent advancements in computational methods have increased the complexity and size of simulations. Our objective is to develop a flexible flow visualization tool for fluid simulations that include the full physics and geometrical complexities found in modeling practical combustion systems, such as internal combustion engines. The challenges to flow visualization come from: (1) the large simulation output, especially when using massively parallel computers; (2) the increasingly complex geometries that include moving surfaces such as pistons and valves; (3) the complex physical phenomena in realistic problems of fuel injection, combustion fronts, boundary flows, and large scale turbulence; and (4) the numerical complexity of indirect addressing of computational elements, variable mesh connectivity, distorted elements, and moving meshes. We have developed a visualization program that addresses these complexities. The program was developed as a post-processor to the KIVA family of codes for reactive flow simulations. Because of the complexity of the KIVA codes, the visualization program is very versatile and applicable to any code with meshes of arbitrary hexahedrons. No comparable commercial visualization package could be found. To visualize the fluid flow, we use massless tracer particles that follow the movement of the fluid as determined from output files from the simulation. The movement of the tracer particles is based on a second-order spatial and temporal interpolation of the fluid velocities from successive simulation output files. The visualization program runs on a Silicon Graphics IRIS GTX workstation. DOE

(NASA-TM-106814; E-9340; NAS 1.15:106814) Avail: CASI HC A03/MF A01

Low-gravity, gas-liquid flow research can be conducted aboard the NASA Lewis Learjet, the Lewis DC-9, or the Johnson Space Center KC-135. Air and water solutions serve as the test liquids in cylindrical test sections with an inner diameter of 1.27 cm and lengths up to 1.5 m. Superficial velocities range from 0.1 to 1.1 m/sec for liquids and from 0.1 to 25 m/sec for air. Flow rate, differential pressure, void fraction, film thickness, wall-shear stress, and acceleration data are measured and recorded throughout the 20 sec duration of the experiment. Flow is visualized by photographing at 400 frames with a high-speed, 16-mm camera. Author

A SUMMARY OF COMPUTATIONAL EXPERIENCE AT GE AIRCRAFT ENGINES FOR COMPLEX TURBULENT FLOWS IN GAS TURBINES

Ronald D. Zerkle and Chander Prakash *In* NASA. Lewis Research Center, Industry-Wide Workshop on Computational Turbulence Modeling Mar. 1995 p 39-46 (For primary document see N95-27882 09-34)
Avail: CASI HC A02/MF A03

This viewgraph presentation summarizes some CFD experience at GE Aircraft Engines for flows in the primary gaspath of a gas turbine engine and in turbine blade cooling passages. It is concluded that application of the standard k-epsilon turbulence model with wall functions is not adequate for accurate CFD simulation of aerodynamic performance and heat transfer in the primary gas path of a gas turbine engine. New models are required in the near-wall region which include more physics than wall functions. The two-layer modeling approach appears attractive because of its computational complexity. In addition, improved CFD simulation of film cooling and turbine blade internal cooling passages will require anisotropic turbulence models. New turbulence models must be practical in order to have a significant impact on the engine design process. A coordinated turbulence modeling effort between NASA centers would be beneficial to the gas turbine industry. Derived from text

THE APPLICABILITY OF TURBULENCE MODELS TO AERODYNAMIC AND PROPULSION FLOWFIELDS AT MCDONNELL-DOUGLAS AEROSPACE

Linda D. Kral, John A. Ladd, and Mori Mani *In* NASA. Lewis Research Center, Industry-Wide Workshop on Computational Turbulence Modeling Mar. 1995 p 47-63 (For primary document see N95-27882 09-34)
Avail: CASI HC A03/MF A03

The objective of this viewgraph presentation is to evaluate turbulence models for integrated aircraft components such as the forebody, wing, inlet, diffuser, nozzle, and afterbody. The one-equation models have replaced the algebraic models as the baseline turbulence models. The Spalart-Allmaras one-equation model consistently performs better than the Baldwin-Barth model, particularly in the log-layer and free shear layers. Also, the Sparlart-Allmaras model is not grid dependent like the Baldwin-Barth model. No general turbulence model exists for all engineering applications. The Spalart-Allmaras one-equation model and the Chien k-epsilon models are the preferred turbulence models. Although the two-equation models often better predict the flow field, they may take from two to five times the CPU time. Future directions are in further benchmarking the Menter blended k-w/k-epsilon and algorithmic improvements to reduce CPU time of the two-equation model. Derived from text

Avail: CASI HC A03/MF A03

This viewgraph presentation discusses (1) turbulence modeling: challenges in turbulence modeling, desirable attributes of turbulence models, turbulence models in FLUENT, and examples using FLUENT; and (2) combustion modeling: turbulence-chemistry interaction and FLUENT equilibrium model. As of now, three turbulence models are provided: the conventional k-epsilon model, the renormalization group model, and the Reynolds-stress model. The renormalization group k-epsilon model has broadened the range of applicability of two-equation turbulence models. The Reynolds-stress model has proved useful for strongly anisotropic flows such as those encountered in cyclones, swirlers, and combustors. Issues remain, such as near-wall closure, with all classes of models.

A COMPOSITION JOINT PDF METHOD FOR THE MODELING OF SPRAY FLAMES
M. S. Raju *In* NASA. Lewis Research Center, Industry-Wide Workshop on Computational Turbulence Modeling Mar. 1995 p 259-268 (For primary document see N95-27882 09-34)
Avail: CASI HC A02/MF A03

This viewgraph presentation discusses an extension of the probability density function (PDF) method to the modeling of spray flames to evaluate the limitations and capabilities of this method in the modeling of gas-turbine combustor flows. The comparisons show that the general features of the flowfield are correctly predicted by the present solution procedure. The present solution appears to provide a better representation of the temperature field, particularly, in the reverse-velocity zone. The overpredictions in the centerline velocity could be attributed to the following reasons: (1) the use of k-epsilon turbulence model is known to be less precise in highly swirling flows and (2) the swirl number used here is reported to be estimated rather than measured. A NUMERICAL METHOD FOR SOLVING THE THREE-DIMENSIONAL PARABOLIZED NAVIER-STOKES EQUATIONS Final Report
Domenic DAmbrosio and Robert Marsilio May 1995 24 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198159; NAS 1.26:198159; ICASE-95-38) Avail: CASI HC A03/MF A01

A numerical technique that solves the parabolized form of the Navier-Stokes equations is presented. Such a method makes it possible to obtain very detailed descriptions of the flowfield in a relatively modest CPU time. The present approach is based on a space-marching technique, uses a finite volume discretization and an upwind flux-difference splitting scheme for the evaluation of the inviscid fluxes. Second order accuracy is achieved following the guidelines of the the ENO schemes. The methodology is used to investigate three-dimensional supersonic viscous flows over symmetric corners. Primary and secondary streamwise vortical structures embedded in the boundary layer and originated by the interaction with shock waves are detected and studied. For purpose of validation, results are compared with experimental data extracted from literature. The agreement is found to be satisfactory. In conclusion, the numerical method proposed seems to be promising as it permits, at a reasonable computational expense, investigation of complex three-dimensional flowfields in great detail. Author

SMALL ANGLE X RAY SCATTERING STUDIES OF REVERSE MICELLES IN SUPERCRITICAL FLUIDS
D. M. Pfund and J. L. Fulton Oct. 1994 10 p Presented at the 3rd International Symposium on Supercritical Fluids, Strasbourg, France, 17-19 Oct. 1994
(Contract DE-AC06-76RL-01830)
(DE95-007803; PNL-SA-25782; CONF-9410114-6) Avail: CASI HC A02/MF A01

The nature of aggregates formed in a supercritical fluid determines its solvent power and selectivity. Small angle X ray scattering (SAXS) is a powerful tool for studying the properties of aggregates with sizes in the 10(angstrom) to 200(angstrom) range. It is also useful in studying those interparticle interactions which operate over a similar distance. The authors have used SAXS to examine the aggregates formed in pure fluids, in mixtures and in fluid/surfactant/water systems. The scattered intensity as a function of angle depends on the geometry, polydispersity, X ray contrast, and interaction strength of the particles as well as on the phase behavior of the system. In this paper the authors present the results of modeling the X-ray scattering from AOT/water reverse micelles in supercritical propane and in propane/carbon dioxide mixtures. They examine the effect of dilution with CO_2 anti-solvent on the phase behavior of the system and on the strength of intermicellar attractions. A better understanding of these systems must be obtained before the applications of supercritical reverse micelle systems to extractions, reactions, and enhanced oil recovery can be fully developed. (Contract DE-FG05-80ET-53088)
(DE95-006166; DOE/ET-53088/686; IFSR-686) Avail: CASI HC A03/MF A01

The authors consider stability problems arising in fluids, plasmas and stellar systems that contain singularities resulting from wave-mean flow or wave-particle resonances. Such resonances lead to singularities in the differential equations determining the normal modes at the so-called critical points or layers. The locations of the singularities are determined by the eigenvalue of the problem, and as a result, the spectrum of eigenvalues forms a continuum. They outline a method to construct the singular eigenfunctions comprising the continuum for a variety of problems. DOE

NUMERICAL SIMULATION OF COUPLED FLOW AND TRANSPORT WITH TOUGH2: A VERIFICATION STUDY
C. M. Oldenburg and K. Pruess Oct. 1994 23 p
(Contract DE-AC03-76SF-00098)
(DE95-008351; LBL-35273) Avail: CASI HC A03/MF A01

We have tested T2DM, the dispersion module of TOUGH2, on two classic flow problems: (1) the seawater intrusion problem of Henry (1964); and (2) the pure solutal free convection problem of Elder (1967). T2DM produces results in agreement with prior work for similar spatial discretizations. In the Henry problem, finer spatial discretization allows the seawater tongue to penetrate slightly farther without affecting the overall flow dynamics. In the strongly coupled pure solutal free convection problem of Elder, results produced by T2DM using high-resolution grids differ markedly from lower-resolution results. These high-resolution simulations agree closely with laboratory experiments. DOE

A PHENOMENOLOGICAL TREATMENT OF ROTATING TURBULENCE Final Report
Ye Zhou May 1995 14 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198168; NAS 1.26:198168; ICASE-95-43) Avail: CASI HC A03/MF A01

The strong similarity between the magnetohydrodynamic (MHD) turbulence and initially isotropic turbulence subject to rotation is noted. We then apply the MHD phenomenologies of Kraichnan and Matthaeus & Zhou to rotating turbulence. When the turbulence is subject to a strong rotation, the energy spectrum is found to scale as E(k) = C(sub Omega)(Omega(sub epsilon))(sup 1/2)k(sup -2), where Omega is the rotation rate, k is the wavenumber, and epsilon is the dissipation rate. This spectral form is consistent with a recent letter by Zeman. However, here the constant C(sub Omega) is found to be related to the Kolmogorov constant and is estimated in the range 1.22 - 1.87 for the typical values of the latter constant. A 'rule' that relates spectral transfer times to the eddy turnover time and the time scale for decay of the triple correlations is deduced. A hypothesis for the triple correlation decay rate leads to the spectral law which varies between the '-5/3' (without rotation) and '-2' laws (with strong rotation). For intermediate rotation rates, the spectrum varies according to the value of a dimensionless parameter that measures the strength of the rotation wavenumber k(sub Omega) = (Omega(sup 3)/epsiolon)(sup 1/2) relative to the wavenumber k. An eddy viscosity is derived with an explicit dependence on the rotation rate. Author

[MODELING THE SHOCK RESPONSE OF SUBMERGED STRUCTURES] Final Report
Jerry H. Ginsburg 15 Dec. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0834)
(AD-A289082) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The task of modelling the shock response of submerged structures has always been implemented in the time domain, in constrast to the frequency domain approch used for structural acoustic modeling of radiation and scattering. One approach used to create time domain representations of the interaction of the structure and the surrounding fluid is to develop a finite element simulation in which a large domain of the fluid is included in the mesh. Because this procedure leads to a very large model that strains avaiable computer resources, it limits the fidelity with which the structure may be modeled. For this reason approximate procedures that replace the fluid with an impedance-type conditions have been derived. Of these, the most widely implemented is the doubly-asymptotic approximation (DAA), which has been developed in a variety of versions. This paper discusses a method for testing the accuracy of DAA in modeling fluid-structure interaction for realistically shape submerged structure. The approach uses the frequency-domain equivalent of the time-domain DAA differential equations, and then compares it to the results obtained from a standard structural acoustics approach of known accuracy. STRUCTURE OF HIGH-SPEED SPRAYS Final Technical Report, 15 Dec. 1984 - 14 Feb. 1989
Frediano V. Bracco Jan. 1995 119 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAG29-85-K-0028)
(AD-A291696; ARO-21781.10-EG) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This work covered both measurements and computations and its results are documented in eight appendices. Measurements were made of drop velocity in vaporizing, steady, full-cone sprays and of drop velocity and drop size in non-vaporizing steady full-cone sprays. In similar conditions, measurements had previously been made of the intact core and of the size of the drops in the immediate vicinity of the injector, thus generating an extensive set of data which were particularly useful for the assessment and the development of multidimensional models of engine sprays. On the computational side, a line source technique was introduced to simulate the intact-core in engine sprays and two extensive numerical studies were carried out to explain the strong anisotropy of the drop velocity fluctuations that had been found in the measurements. In another interesting and timely study, the accuracy of the stochastic method of computing drop collisions and coalescence (which is the one universally used) was assessed by corresponding deterministic computations (more accurate but much more time consuming). It was concluded that the accuracy of the stochastic method in practical computations can be wanting. Finally, a numerical study of the structure of hollow-cone sprays was initiated that has since been followed by significant experimental and computational work on liquid-only and air-assisted hollow-cone injectors and sprays. THIRD-ORDER-ACCURATE NUMERICAL METHODS FOR EFFICIENT, LARGE TIME-STEP SOLUTIONS OF MIXED LINEAR AND NONLINEAR PROBLEMS
J. W. Cobb Feb. 1995 52 p
(Contract DE-AC05-84OR-21400)
(DE95-009184; ORNL/TM-12891) Avail: CASI HC A04/MF A01

There is an increasing need for more accurate numerical methods for large-scale nonlinear magneto-fluid turbulence calculations. These methods should not only increase the current state of the art in terms of accuracy, but should also continue to optimize other desired properties such as simplicity, minimized computation, minimized memory requirements, and robust stability. This includes the ability to stably solve stiff problems with long time-steps. This work discusses a general methodology for deriving higher-order numerical methods. It also discusses how the selection of various choices can affect the desired properties. The explicit discussion focuses on third-order Runge-Kutta methods, including general solutions and five examples. The study investigates the linear numerical analysis of these methods, including their accuracy, general stability, and stiff stability. Additional appendices discuss linear multistep methods, discuss directions for further work, and exhibit numerical analysis results for some other commonly used lower-order methods. DOE

A GENUINELY MULTIDIMENSIONAL UPWIND SCHEME AND EFFICIENT MULTIGRID SOLVER FOR THE COMPRESSIBLE EULER EQUATIONS
David Sidilkover Nov. 1994 37 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract NAS1-19480)
(NASA-CR-195000; NAS 1.26:195000; AD-A289712; ICASE-94-84) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We present a new approach towards the construction of a genuinely multidimensional high-resolution scheme for computing steady-state solutions of the Euler equations of gas dynamics. The unique advantage of this approach is that the Gauss-Seidel relaxation is stable when applied directly to the high-resolution discrete equations, thus allowing us to construct a very efficient and simple multigrid steady-state solver. This is the only high-resolution scheme known to us that has this property. The two-dimensional scheme is presented in detail. It is formulated on triangular (structured and unstructured) meshes and can be interpreted as a genuinely two-dimensional extension of the Roe scheme. The quality of the solutions obtained using this scheme and the performance of the multigrid algorithm are illustrated by the numerical experiments. Construction of the three dimensional scheme is outlined briefly as well. DTIC

(DE95-006837; LA-12896) Avail: CASI HC A10/MF A03

This report describes an extensive program of investigations conducted at Arzamas-16 in Russia over the past several decades. The focus of the work is on material interface instability and the mixing of two materials. Part 1 of the report discusses analytical and computational studies of hydrodynamic instabilities and turbulent mixing. The EGAK codes are described and results are illustrated for several types of unstable flow. Semiempirical turbulence transport equations are derived for the mixing of two materials, and their capabilities are illustrated for several examples. Part 2 discusses the experimental studies that have been performed to investigate instabilities and turbulent mixing. Shock-tube and jelly techniques are described in considerable detail. Results are presented for many circumstances and configurations. DOE

MONTE-CARLO SIMULATION METHODS FOR FINITE FLAT PLATE WINDING FLOWS
Yuzhong Shi, Qifen Wu, and Bing Ren 15 Nov. 1994 18 p Transl. into ENGLISH from Kongqidonglixue Xuebao, China, v. 9, no. 3, Sep. 1991 p 324-329 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289842; NAIC-ID(RS)T-0919-92) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This article opts for the use of direct simulation Monte-Carlo methods to solve such problems as those associated with winding flows around flat plates of finite length. The methods in question are ones which go through tracking the movements of simulated molecules by computer in order to realize numerical value simulations. Collision calculations between simulated molecules are determined from statistical samplings. As far as collision models are concerned, respective selections were made for the use of hard sphere molecule models and inverse power law models. As far as simulation molecule and solid wall effects are concerned, option was made for the use of models which are made up from mixtures on the basis of ratios of fully diffused reflection and specular or mirror surface reflection. For the sake of the reliability of empirical test methods, calculations were also done of the one dimensional flow movements associated with such questions and Rayleigh problems and shock wave structures. Two dimensional calculations opted for the use of synchronous parallel programs. Numerical value results clearly showed that direct simulation Monte-Carlo methods were capable of relatively good simulations of a number of problems in rarefied gas mechanics. As far as two dimensional calculations are concerned, the machine time expended and the necessary content are both within ranges permitted by domestic machines. DTIC

EXPERIMENTAL STUDY ON TRANSITION CHARACTERISTICS OF NATURAL-CONVECTION FLOW Ph.D. Thesis
I. J. Opstelten 17 Oct. 1994 150 p
(PB95-192423; ISBN-90-9007545-3) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In this thesis, an experimental study on transition characteristics of natural-convection flow in cubical cavities is described. Natural convection is spoken of when the flow arises from the force of gravity working on density differences in the fluid, as opposed to forced convection, where the flow arises from pressure differences. The density differences can be due to different processes, such as concentration differences of chemical elements, a mixture of various fluids, or multiphase flows. Another common source for density differences is temperature differences in a fluid. Such temperature differences can occur in various technical applications, such as cooling of electronic equipment, heat transfer in solar collectors, insulation by double-glazed windows and climate control in buildings and greenhouses. The natural-convection flow investigated in this work is a result from temperature differences too. NTIS

RESPONSE OF MULTI-PANEL ASSEMBLY TO NOISE FROM A JET IN FORWARD MOTION Final Report
A. Bayliss (Northwestern Univ., Evanston, IL.), L. Maestrello (National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.), J. L. McGreevy (Philadelphia Coll. of Pharmacy and Science, PA.), and C. C. Fenno, Jr. (National Academy of Sciences - National Research Council, Hampton, VA.) May 1995 30 p Submitted for publication
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198164; NAS 1.26:198164; ICASE-95-41) Avail: CASI HC A03/MF A01

A model of the interaction of the noise from a spreading subsonic jet with a 4 panel assembly is studied numerically in two dimensions. The effect of forward motion of the jet is accounted for by considering a uniform flow field superimposed on a mean jet exit profile. The jet is initially excited by a pulse-like source inserted into the flow field. The pulse triggers instabilities associated with the inviscid instability of the jet shear layer. These instabilities generate sound which in turn serves to excite the panels. We compare the sound from the jet, the responses of the panels and the resulting acoustic radiation for the static jet and the jet in forward motion. The far field acoustic radiation, the panel response and sound radiated from the panels are all computed and compared to computations of a static jet. The results demonstrate that for a jet in forward motion there is a reduction in sound in downstream directions and an increase in sound in upstream directions in agreement with experiments. Furthermore, the panel response and radiation for a jet in forward motion exhibits a downstream attenuation as compared with the static case. Author

PERFORMANCE MODELING OF HYPERSPECTRAL IMAGING SENSORS FOR ATMOSPHERIC STUDIES Final Technical Report
Yudi Adityawarman and R. A. Schowengerdt Sep. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-G004)
(AD-A289017) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In this research project, we have developed a sensor model for the

Navy's HYDICE system, using current engineering specifications and data from Hughes Danbury Optical Systems, the manufacturer. This sensor imaging model has been integrated into an end-to-end simulation system, Multispectral Image Simulator (MIS). Using MIS with the HYDICE model we have investigated Signal to Noise Ratios (SNR's) that might be expected from HYDICE under low radiance conditions, such as images of coastal water areas. The results are presented in Section 4.1. We also used the Cuprite, Nevada, AVIRIS database developed earlier, for simulation of natural HYDICE imagery. This is presented in Section 4.2. Finally, we have also initiated investigation of large view angle effects on image contrast, using the Advanced Very High Resolution Radiometer (AVHRR) module in MIS since it allows a range of +55 deg in view angle cross-track. These simulation results are presented in Section 4.3. DTIC

LARGE AREA SMART PIEZOELECTRIC AND PYROELECTRIC SENSORS Interim Report, No. 6

D. K. Das-Gupta and M. P. Wenger Nov. 1994 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract DAJA45-93-C-0017)

(AD-A288565; R/D-6980-EE-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The nature of the pyroelectric properties of the composite %Ca/Epikote 828 with 50/50 and 60/40 percent volume was reported in the fifth interim report. The present report provides an account of the preparation of pure lead titanate (H) and calcium modified lead titanate (%Ca) by the Sol-Gel process. X-ray Spectroscopic Structural Analysis and Differential Scanning Calorimetric (DSC) studies of the ceramic grains produced by this technique were made and the results are given in this report. The Sol-Gel method for preparation of ferroelectric ceramics can offer many advantages over conventional processing techniques. Ceramics produced via the Sol-Gel method show high degrees of purity and homogeneity, can produce fine powders as well as being able to be formed into a variety of structures and they possess the ability to be processed at lower temperatures. THE DEVELOPMENT OF INFRARED DETECTORS AND MECHANISMS FOR USE IN FUTURE INFRARED SPACE MISSIONS Final Report

James R. Houck 27 Apr. 1995 15 p

(Grant NAGw-2870)

(NASA-CR-197819; NAS 1.26:197819) Avail: CASI HC A03/MF A01

The environment above earth's atmosphere offers significant advantages in sensitivity and wavelength coverage in infrared astronomy over ground-based observatories. In support of future infrared space missions, technology development efforts were undertaken to develop detectors sensitive to radiation between 2.5 micron and 200 micron. Additionally, work was undertaken to develop mechanisms supporting the imaging and spectroscopy requirements of infrared space missions. Arsenic-doped-Silicon and Antimony-doped-Silicon Blocked Impurity Band detectors, responsive to radiation between 4 micron and 45 micron, were produced in 128x128 picture element arrays with the low noise, high sensitivity performance needed for space environments. Technology development continued on Gallium-doped-Germanium detectors (for use between 80 micron and 200 micron), but were hampered by contamination during manufacture. Antimony-doped-Indium detectors (for use between 2.5 micron and 5 micron) were developed in a 256x256 pixel format with high responsive quantum efficiency and low dark current. Work began on adapting an existing cryogenic mechanism design for space-based missions; then was redirected towards an all-fixed optical design to improve reliability and lower projected mission costs. EVALUATION OF A NEW LABORATORY ACOUSTIC DOPPLER VELOCIMETER M.S. Thesis

Gary N. Underwood Dec. 1994 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289592) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A small, rugged and relatively inexpensive velocity meter has been developed to measure uniform and oscillatory water flows in laboratory facilities. The Acoustic Doppler Velocimeter (ADV-1) is capable of measuring three-dimensional velocities. The ADV-1 measures velocities from 0 to 2.5 m/s at a sampling rate of up to 25 Hz. The measurements are made in a sampling volume located 5 cm in front of the probe. Since this instrument is new, the objective is to compare the ADV-1 with other laboratory current meters and prepare operational guidelines for the ADV-1 system. Three-dimensional velocities are measured in a wave tank with the ADV-1 horizontal velocity average 0.9 cm/s higher than the laser Doppler anemometer (LDA) and the ADV-1 vertical velocity average 0.93 cm/s lower than the LDA. A horizontal velocity profile is measured in a wave flume by the ADV-1 and a pitot tube, and the instruments differ by 3.5%. Measuring velocity profiles around a stationary cylinder with the ADV-1 in the wave flume was highly successful, showing the ability of this instrument to measure velocities near structures in future laboratory research. The ADV-1 is portable and can be used for extended periods without recalibration. DTIC

METHOD AND APPARATUS FOR POLARADIOMETRIC PYROMETER Patent Application

Ali A. Abtahi, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena, CA.) 22 Jun. 1994 20 p

(NASA-Case-NPO-19064-1-CU; NAS 1.71:NPO-19064-1-CU; US-Patent-Appl-SN-273542) Avail: CASI HC A03/MF A01

A radiation pyrometer for measuring the true temperature of a body is provided by detecting and measuring thermal radiation from the body based on the principle that the effects of angular emission I(sub 1) and reflection I(sub 2) on the polarization states p and s of radiation are complementary such that upon detecting the combined partial polarization state components I(sub p) = I(sub 1p) + I(sub 2p) and I(sub s) = I(sub 1s) + I(sub 2s) and adjusting the intensity of the variable radiation source of the reflected radiation I(sub 2) until the combined partial radiation components I(sub p) and I(sub s) are equal, the effects of emissivity as well as diffusivity of the surface of the body are eliminated, thus obviating the need for any post processing of brightness temperature data. BORON-INDUCED MORPHOLOGY CHANGES IN SILICON CVD GROWTH: A SCANNING TUNNELING MICROSCOPY STUDY Interim Report

Robert J. Hamers and Yajun Wang 20 Dec. 1994 10 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract N00014-91-J-1629)

(AD-A289275; TR-24) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Scanning tunneling microscopy has been used to investigate the influence of surface boron on silicon growth via chemical vapor deposition (CVD). The presence of boron-induced reconstructions on the Si(001) surface dramatically changes the surface morphology during subsequent CVD growth of silicon using disilane at 815 Kelvin. Boron-induced reconstructions inhibit the lateral diffusion of silicon atoms from terraces to step edges, leading to greatly enhanced island nucleation, and also reduce the local surface reactivity toward disilane. Strong segregation of boron to the growth surface allows the enhanced island nucleation to persist to subsequent terraces during multilayer CVD growth of silicon, producing a rough but epitaxial surface. DISTRIBUTED INTERACTIVE SIMULATION VIRTUAL CASSETTE RECORDER (DIS VCR); A DATALOGGER WITH VARIABLE SPEED REPLAY M.S. Thesis

Jonathan L. Fortner Dec. 1994 106 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289212; AFIT/GE/ENG/94D-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The overall objective of the Distributed Interactive Simulation Virtual Cassette Recorder (DIS VCR) is to add a flexible replay capability to any

DIS environment and specifically to the Remote Debriefing Tool (RDT). The DIS VCR's abilities include selective filtering of incoming DIS Protocol Data Units (PDUs), variable-speed replays, ability to pause, fast-forward, rewind, efficient data storage and retrieval, and an interface that simplifies the execution of those functions. The thesis includes a DIS VCR-compatible design for concurrent replay of audio extracted from signal PDUs and an extension to the replay design that supports unmodifiable rendering or receiving applications. For variable-speed replays, the authors created a scalable simulation clock and a new PDU (the Replay PDU). Applications modified for replays use the simulation clock to govern their dead reckoning algorithms while the DIS VCR uses it to control the timed release of stored PDUs. The Replay PDU communicates mode and speed changes between the DIS VCR and replay-modified applications. The DIS VCR's full functionality was successfully demonstrated at the 1994 AFA convention. CRYOGENIC AND SIMULATED FUEL JET BREAKUP IN ARGON, HELIUM AND NITROGEN GAS FLOWS

Robert D. Ingebo May 1995 15 p Presented at the 31st Joint Propulsion Conference, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, AND ASEE
(RTOP 505-62-52)
(NASA-TM-106923; E-9636; NAS 1.15:106923; AIAA Paper 95-2554)
Avail: CASI HC A03/MF A01

Two-phase flow atomization of liquid nitrogen jets was experimentally investigated. They were co-axially injected into high-velocity gas flows of helium, nitrogen and argon, respectively, and atomized internally inside a two-fluid fuel nozzle. Cryogenic sprays with relatively high specific surface areas were produced, i.e., ratios of surface area to volume were fairly high. This was indicated by values of reciprocal Sauter mean diameters, RSMD's, as measured with a scattered- light scanning instrument developed at NASA Lewis Research Center. Correlating expressions were derived for the three atomizing gases over a gas temperature range of 111 to 422 K. Also, the correlation was extended to include waterjet breakup data that had been previously obtained in simulating fuel jet breakup in sonic velocity gas flow. The final correlating expression included a new dimensionless molecular-scale acceleration group. It was needed to correlate RSMD data, for LN2 and H2O sprays, with the fluid properties of the liquid jets and atomizing gases used in this investigation. Author

MULTI-CHANNEL ELECTRONICALLY SCANNED CRYOGENIC PRESSURE SENSOR Patent Application

John J. Chapman, inventor (to NASA) (Chapman, John J., Wareneck, VA.), Purnell Hopson, Jr., inventor (to NASA) (Hopson, Purnell, Jr., Seaford, VA.), and Nancy M. H. Kruse, inventor (to NASA) (Kruse, Nancy M. H., Hayes, VA.) 4 Apr. 1995 27 p
(NASA-Case-LAR-15062-1; NAS 1.71:LAR-15062-1;
US-Patent-Appl-SN-416596) Avail: CASI HC A03/MF A01

A miniature, multi-channel, electronically scanned pressure measuring device uses electrostatically bonded silicon dies in a multielement array. These dies are bonded at specific sites on a glass, prepatterned substrate. Thermal data is multiplexed and recorded on each individual pressure measuring diaphragm. The device functions in a cryogenic environment without the need of heaters to keep the sensor at constant temperatures. NASA

FUZZY INFERENCE ENHANCED INFORMATION RECOVERY FROM DIGITAL PIV USING CROSS-CORRELATION COMBINED WITH PARTICLE TRACKING

Mark P. Wernet May 1995 17 p Presented at Conference on Optical Techniques in Fluid, Thermal and Combusting Flows, San Diego, CA, 9-14 Jul. 1995; sponsored by the Society for Photo-Optical Instrumentation Engineers Original contains color illustrations
(RTOP 505-62-50)
(NASA-TM-106896; E-9544; NAS 1.15:106896) Avail: CASI HC A03/MF A01; 3 functional color pages

Particle Image Velocimetry provides a means of measuring the instantaneous 2-component velocity field across a planar region of a seeded flowfield. In this work only two camera, single exposure images are considered where both cameras have the same view of the illumination plane. Two competing techniques which yield unambiguous velocity vector direction information have been widely used for reducing the single exposure, multiple image data: cross-correlation and particle tracking. Correlation techniques yield averaged velocity estimates over subregions of the flow, whereas particle tracking techniques give individual particle velocity estimates. The correlation technique requires identification of the correlation peak on the correlation plane corresponding to the average displacement of particles across the subregion. Noise on the images and particle dropout contribute to spurious peaks on the correlation plane, leading to misidentification of the true correlation peak. The subsequent velocity vector maps contain spurious vectors where the displacement peaks have been improperly identified. Typically these spurious vectors are replaced by a weighted average of the neighboring vectors, thereby decreasing the independence of the measurements. In this work fuzzy logic techniques are used to determine the true correlation displacement peak even when it is not the maximum peak on the correlation plane, hence maximizing the information recovery from the correlation operation, maintaining the number of independent measurements and minimizing the number of spurious velocity vectors. Correlation peaks are correctly identified in both high and low seed density cases. The correlation velocity vector map can then be used as a guide for the particle tracking operation. Again fuzzy logic techniques are used, this time to identify the correct particle image pairings between exposures to determine particle displacements, and thus velocity. The advantage of this technique is the improved spatial resolution which is available from the particle tracking operation. Particle tracking alone may not be possible in the high seed density images typically required for achieving good results from the correlation technique. This two staged approach offers a velocimetric technique capable of measuring particle velocities with high spatial resolution over a broad range of seeding densities. Author

SCHLIEREN SYSTEM AND METHOD FOR MOVING OBJECTS Patent Application

Leonard M. Weinstein, inventor (to NASA) 14 Feb. 1995 14 p
(NASA-Case-LAR-15053-1; NAS 1.71:LAR-15053-1;
US-Patent-Appl-SN-388652) Avail: CASI HC A03/MF A01

A system and method are provided for recording density changes in a flow field surrounding a moving object. A mask having an aperture for regulating the passage of images is placed in front of an image recording medium. An optical system is placed in front of the mask. A transition having a light field-of-view and a dark field-of-view is located beyond the test object. The optical system focuses an image of the transition at the mask such that the aperture causes a band of light to be defined on the image recording medium. The optical system further focuses an image of the object through the aperture of the mask so that the image of the object appears on the image recording medium. Relative motion is minimized between the mask and the transition. Relative motion is also minimized between the image recording medium and the image of the object. In this way, the image of the object and density changes in a flow field surrounding the object are recorded on the image recording medium when the object crosses the transition in front of the optical system. HIGH-PRECISION BUFFER CIRCUIT FOR SUPPRESSION OF REGENERATIVE OSCILLATION

John S. Tripp, David A. Hare, and Ping Tcheng May 1995 18 p
(RTOP 505-59-54-02)
(NASA-TM-4658; L-17453; NAS 1.15:4658) Avail: CASI HC A03/MF A01

Precision analog signal conditioning electronics have been developed for wind tunnel model attitude inertial sensors. This application requires low-noise, stable, microvolt-level DC performance and a high-precision buffered output. Capacitive loading of the operational amplifier output stages due to the wind tunnel analog signal distribution facilities caused regenerative oscillation and consequent rectification bias errors. Oscillation suppression techniques commonly used in audio applications were inadequate to maintain the performance requirements for the measurement of attitude for wind tunnel models. Feedback control theory is applied to develop a suppression technique based on a known compensation (snubber) circuit, which provides superior oscillation suppression with high output isolation and preserves the low-noise low-offset performance of the signal conditioning electronics. A practical design technique is developed to select the parameters for the compensation circuit to suppress regenerative oscillation occurring when typical shielded cable loads are driven. Author

STUDY OF DEVELOPMENT AND UTILIZATION OF A MULTIPURPOSE ATMOSPHERIC CORROSION SENSOR Annual Research Technical Report
Ravinder M. Diwan, A. Raman, and P. K. Bhattacharya Dec. 1994 55 p
(Grant NAG10-0127)
(NASA-CR-198595; NAS 1.26:198595) Avail: CASI HC A04/MF A01

There has been a critical need for analyzing various aspects of atmospheric corrosion and for the development of atmospheric corrosion microsensors. The project work has involved the following activities: (1) making of multielectrode corrosion monitors on dielectric substrates; (2) testing them in the laboratory for functional characteristics; (3) preparing a report on the state of the art of atmospheric corrosion sensor development around the world; and (4) corrosion testing of electrochemical changes of sensor specimens and related fog testing. The study included work on the subject of development and utilization of a multipurpose atmospheric corrosion sensor and this report is the annual report on work carried out on this research project. This has included studies on the development of sensors of two designs, stage 1 and stage 2, and with glass and alumina substrate, experimentation and development and characterization of the coating uniformity, aspects of corrosion monitoring, literature search on the corrosion sensors and their development. A state of the art report on atmospheric corrosion sensor development was prepared and submitted. Derived from text

INTRUSIVE MULTI-PROBE SYSTEM
R. A. Green, L. R. Hester, and C. W. Bouchillon 1995 30 p
(Contract DE-AC02-80ET-15601)
(DE95-006258; DOE/ET-15601/T63) Avail: CASI HC A03/MF A01

The Diagnostic Instrumentation and Analysis Laboratory (DIAL) in the College of Engineering at Mississippi State University is the result of the efforts of several faculty members in the Aerospace and Chemical Engineering Departments obtaining funding in 1976. At that time, an initial research project was begun which was funded by the US Department of Energy as part of the national magnetohydrodynamic (MHD) program. Initial research efforts concentrated in heat recovery and seed recovery (HRSR) from the MHD combustion process as well as some materials investigations. Over the years, efforts at DIAL were shifted from HRSR studies to the development of optical based, microprocessor controlled instrumentation for use in the harsh MHD environment. DOE

THE KTeV PURE CsI CALORIMETER
Ronald E. Ray Dec. 1994 8 p Presented at the 5th International Conference on Calorimetry in High Energy Physics, Upton, NY, 25 Sep. - 1 Oct. 1994; sponsored by Brookhaven National Lab.
(Contract DE-AC02-76CH-03000)
(DE95-005747; FNAL/C-94/418; CONF-9409268-7) Avail: CASI HC A02/MF A01

KTeV is currently building a state-of-the-art pure CsI electromagnetic calorimeter with a sophisticated digital readout. The CsI array is expected to have better than 1% resolution over a dynamic range of 2-64 GeV. The design of the CsI array is driven by the difficult physics goal of attempting to measure the CP violation parameter Re(epsilon'/epsilon) to 1 part in 10000 in a high-rate neutral beam environment. The physics requirements and their impact on the final design will be discussed. DOE

OPTIMIZATION OF MEASUREMENTS WITH PRESSURE SENSITIVE PAINTS

Donald M. Oglesby (Old Dominion Univ., Norfolk, VA.), Chith K. Puram (Vigyan Research Associates, Inc., Hampton, VA.), and Billy T. Upchurch Jun. 1995 9 p
(RTOP 505-59-54-02)
(NASA-TM-4695; L-17474; NAS 1.15:4695) Avail: CASI HC A02/MF A01

Use of luminescent paints for the measurement of global pressures on wind tunnel model surfaces requires a full understanding of the inherent accuracy of the technique. Theoretical emission of the paint luminophor follows the well known Stern-Volmer relation. Inherent in this relation are fundamental limits to achievable sensitivity and accuracy. Equations for relative error in pressure as a function of relative signal intensity (emittance), relative error in pressure as a function of pressure, and the relationship between sensitivity and pressure are derived and represented graphically.

A PHASE-STEPPED POINT DIFFRACTION INTERFEROMETER USING LIQUID CRYSTALS

Carolyn R. Mercer, Katherine Creath (Arizona Univ., Tucson, AZ.), and Nasser Rashidnia (NYMA, Inc., Brook Park, OH.) May 1995 9 p Presented at the International Symposium on Optical Science, Engineering, and Instrumentation, San Diego, CA, 9-14 Jul. 1995; sponsored by Society of Photo-Optical Instrumentation Engineers
(Contract NAS3-27186; RTOP 505-62-50)
(NASA-TM-106922; E-9634; NAS 1.15:106922) Avail: CASI HC A02/MF A01

A new instrument, the liquid crystal point diffraction interferometer (LCPDI), has been developed for the measurement of phase objects. This instrument maintains the compact, robust design of Linnik's point diffraction interferometer (PDI) and adds to it phase stepping capability for quantitative interferogram analysis. The result is a compact, simple to align, environmentally insensitive interferometer capable of accurately measuring optical wavefronts with high data density and with automated data reduction. The design of the LCPDI is briefly discussed. An algorithm is presented for eliminating phase measurement error caused by object beam intensity variation from frame-to-frame. The LCPDI is demonstrated by measuring the temperature distribution across a heated chamber filled with silicone oil. The measured results are compared to independently measured results and show excellent agreement with them. It is expected that this instrument will have application in the fluid sciences as a diagnostic tool, particularly in space based applications where autonomy, robustness, and compactness are desirable qualities. It should also be useful for the testing of optical elements, provided a master is available for comparison. Author

CAN TMAE PHOTOCATHODE BE USED FOR HIGH RATE APPLICATIONS?

J. Vavra 1995 6 p Presented at the 7th Vienna Wire Chamber Conference, Vienna, Austria, 13-17 Feb. 1995
(Contract DE-AC03-76SF-00515)
(DE95-008594; SU-SLAC-PUB-95-6759; CONF-950276-1) Avail: CASI HC A02/MF A01

The paper explores the problems associated with wire aging, charging effects, and self-sustaining cathode currents in the TMAE (Tetrakis dimethylamino ethylene) based photodetectors. It is generally believed that anode wire aging is the most serious problem encountered in TMAE-based Cherenkov ring imaging detectors. Although charging effects and self-sustaining cathode currents have not been studied systematically, there is concern that they too could become significant over a long period of time. DOE

A temperature sensor uses a type R thermocouple wire element in a ceramic sheath to sense temperatures up to 3,200 deg F., and is particularly suitable for flexible insulations. The sensor includes a thermocouple wire embedded in a sheath having two sections disposed at right angles to each other. The junction of the thermocouple is located at one end of one of the sections and the lead wires extend from the other section. The section which includes the junction is secured to a flexible surface with ceramic cement.

PARTICLE FALLOUT/ACTIVITY SENSOR Patent

Ihlefeld M. Curtis, inventor (to NASA), Robert C. Youngquist, inventor (to NASA), John S. Moerk, inventor (to NASA), and Kenneth A. Rose, III, inventor (to NASA) 2 May 1995 11 p Filed 26 Apr. 1994
(NASA-Case-KSC-11687-1; US-Patent-5,412,221;
US-Patent-Appl-SN-233584; US-Patent-Class-250-573;
US-Patent-Class-356-338; Int-Patent-Class-G01N-15/06) Avail: US Patent and Trademark Office

A particle fallout/activity sensor measures relative amounts of dust or other particles which collect on a mirror in an area to be monitored. The sensor includes a sensor module and a data acquisition module, both of which can be operated independently of one another or in combination with one another. The sensor module includes a housing containing the mirror, an LED assembly for illuminating the mirror and an optical detector assembly for detecting light scattered off of the mirror by dust or other particles collected thereon. A microprocessor controls operation of the sensor module's components and displays results of a measurement on an LCD display mounted on the housing. A push button switch is also mounted on the housing which permits manual initiation of a measurement. The housing is constructed of light absorbing material, such as black delrin, which minimizes detection of light by the optical detector assembly other than that scattered by dust or particles on the mirror. The data acquisition module can be connected to the sensor module and includes its own microprocessor, a timekeeper and other digital circuitry for causing the sensor module to make a measurement periodically and send the measurement data to the data acquisition module for display and storage in memory for later retrieval and transfer to a separate computer. The time tagged measurement data can also be used to determine the relative level of activity in the monitored area since this level is directly related to the amount of dust or particle fallout in the area.

DESIGN, CONSTRUCTION, TEST AND EVALUATION OF A FREQUENCY SCANNING RADIOMETER FOR MEASURING OIL SLICK THICKNESSES Final Report, Oct. 1992 - Jun. 1994

G. L. Hover, J. Murphy, E. R. Brown, G. G. Hogan, and O. B. McMahon Jun. 1994 141 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-90-C-0002)
(AD-A290040; USCG-D-29-24) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Single frequency microwave radiometry has been used to detect and estimate oil slick thicknesses. Because only a single sampling point is used, estimates of oil thickness can become ambiguous. MIT Lincoln Laboratory proposed the concept of using a frequency scanning radiometer to sample multiple points across a frequency band, thus resolving the problem of ambiguities in oil thickness estimation. A laboratory-prototype FSR capable of scanning over Ka-band (26 -40GHz) was designed, built, and tested. The FSR was used in laboratory proof-of-principle testing to (1) measure uniform thickness oil layers under various ambient weather conditions (day, night, clear, cloudy, drizzle, and snow) and different oil types, and (2) measure the phenomenology of non-uniform thickness oil layers and emulsions. Comparisons of measured data sets with theoretical predictions demonstrated that the expected response of oil is consistent regardless of oil type or ambient weather condition. Comparisons of uniform oil layer measurements and non-uniform measurements with theoretical predictions indicate that the radiometric brightness temperature (TB) of the oil above that of water is a function of the percentage of that thickness of oil within the antenna field-of-view. Water/oil emulsions were measured and have a higher TB than a uniform layer of pure oil at the same thickness. Recommendations for FSR modifications and improvements, as well as future collection work are included. DTIC

AN ORGANIC THIN FILM LASER DIODE: A NOVEL LIGHT SOURCE
N. Peyghambarian, N. R. Armstrong, H. Hall, A. Padias, and S. Mazumdar 28 Nov. 1994 13 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0322)
(AD-A289007; TR-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The development of an entirely new diode laser based upon electroluminescent organic thin films is discussed. The authors proposed to develop new polymers for this important application. As shown below, significant progress was made during the ten first months of this project toward the realization of these challenging objectives. The authors have successfully fabricated a promising LED based on a new aluminum quinolate derivative that emits in the blue-green and that can be dissolved in a polymer matrix and spin-cast. DTIC

The thermal lenses in operating copper vapor lasers and in the fused silica windows were measured by use of the deflection method and the interferometer method respectively. Experimental results show that the overall thermal lens is composed of a negative lens in the discharge gas and two positive lenses in two pieces of laser windows. Theoretical analysis agrees well with experimental results. DTIC

HIGH-SPEED COHERENT LASER ARRAYS Final Report, Jul. 1992 - 1993
Marc K. Felisky, Richard DeFreez, Joseph H. Abeles, Daniel W. Bechtle, and S. Y. Naravan Nov. 1994 54 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F30602-92-C-0111; ARPA Order 8799)
(AD-A289373; RL-TR-94-195) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research describes a novel approach to semiconductor lasers capable of ultra-high speed modulation. This approach uses the interaction between elements in a coherent diode laser array that results in lateral mode locking. This method potentially allows narrow-band modulation at rates above the relaxation oscillation frequency of the lasers, thus removing a major impediment to ultra-high speed modulation. Linearized analysis of coupled laser rate equations shows that the array can be asymptotically stable for values of the coupling attainable with index-guided lasers. The small-signal responsivity for a two-element array, for 180 deg out-of-phase/modulation, extends far beyond the relaxation oscillation frequency when examining the optical output from a single element. Large-signal analysis using full rate equations were used to demonstrate schemes for utilizing these microwave frequency resonances for high-speed optical signal transmissions. It was shown that digital signals with bit rates many times the relaxation oscillation frequency could be transmitted. Using lasers with a 4-GHz relaxation oscillation frequency, it is theoretically shown that rates greater than 25 Gb/s can be achieved. This scheme can also be used for encoding analog information using narrow band amplitude modulation. It was demonstrated that a 44 GHz carrier with a 1-GHz amplitude modulated envelope signal could be successfully implemented (same device parameters as used for the digital example). DTIC

GENERATION OF A SINGLE-LOBE, FAR-FIELD INTENSITY PATTERN FROM A LASER DIODE ARRAY USING AN OPTICAL DELAY LINE M.S. Thesis
Thomas A. Summers Dec. 1994 97 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289226; AFIT/GAP/ENP/94D-10) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A simple and practical technique is demonstrated to generate a stable, single-lobe, far-field intensity pattern from a one-dimensional, antiphased, laser diode array with gain-guided elements. The two far-field lobes of the array are combined after introducing an optical delay line into the path of one of the lobes to make the lobes mutually incoherent. The incoherent superposition of intensities produces a near-diffraction-limited, single-lobe, far-field intensity pattern containing 84% of the power, exceeding any previous (known) phase control experiments. This technique compares favorably with more elaborate schemes advanced previously using integrated phase plates, etc. The method is directly applicable to one-dimensional laser diode arrays and could be adapted for use with two-dimensional arrays as well. LASER BEAM PROPAGATION IN NON-KOLMOGOROV ATMOSPHERIC TURBULENCE M.S. Thesis
Bruce E. Stribling 13 Dec. 1994 91 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289256; AFIT/GEO/ENG/94D-04) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Several observations of atmospheric turbulence statistics have been reported which do not obey Kolmogorov's power spectral density model. These observations have prompted the study of optical propagation through turbulence described by non-classical power spectra. This thesis presents an analysis of optical propagation through turbulence which causes index of refraction fluctuations to have spatial power spectra that obey arbitrary power laws. The spherical and plane wave structure functions are derived using Mellin transform techniques and are applied to the field mutual coherence function (MCF) using the extended Huygens-Fresnel principle. The MCF is used to compute the Strehl ratio of a focused, constant amplitude beam propagating in non-Kolmogorov turbulence as the power law for the spectrum of the index of refraction fluctuations is varied from -3 to -4. The relative contributions of the log amplitude and phase structure functions to the wave structure function are computed. If inner and outer scale effects are neglected, no turbulence exists when the power law equals -3. At power laws close to -3, the magnitude of the log amplitude and phase perturbations are determined by the system Fresnel ratio. At power laws approaching -4, phase effects dominate in the form of random tilts. DTIC

TOWARD COHERENT EXCITATION: DEVELOPMENT OF A SINGLE-SOURCE PUMP FOR THE RUBIDIUM HYPERFINE GROUND STATE DOUBLET M.S. Thesis
Edward B. Tomme Dec. 1994 63 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289413; AFIT/CI/CIA/94-152) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Coherent excitation is a phenomenon which, if achieved, could provide a new tool for the investigation of many fundamental questions in atomic physics and quantum optics. A design which could produce such coherences could lead to applications as varied as lasing without inversion and electromagnetically induced transparency. In this thesis, the basic theory concerning the generation of coherent superpositions of the ground states of atomic rubidium is reviewed. Next, the design, construction, and testing of a Littrow-style grating-tuned laser and a standing wave electro-optic modulator used in generating sidebands at the frequency matching the rubidium hyperfine ground state doublet are described. An experiment demonstrating simultaneous absorption by the Rb-85 F = 2 and Rb-85 F = 3 using a single laser as the pump is chronicled. An experiment to test coherences generated by this method of single-source pumping of the ground state doublet is proposed. DTIC

COLLISIONAL DYNAMICS AND SPECTROSCOPIC STUDIES OF HIGHLY EXCITED ROVIBRATIONAL LEVELS OF I2(X)(0(+)(SUB g)) VIA STIMULATED EMISSION PUMPING Ph.D. Thesis
Melvin L. Nowlin Nov. 1994 309 p Limited Reproducibility: More than

20% of this document may be affected by microfiche quality
(AD-A289447; AFIT/CI/CIA/94-039D) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Highly excited vibrational levels of I2(X) are thought to play an important role in the mechanism of iodine dissociation in the chemical oxygen iodine laser. It has been proposed that I2 is dissociated in the laser with processes such as: (1) I2(X;v(double prime) = 0) + M(*) yields I2(X;v(double prime) greater than 20) + M; (2) I2(X;v(double prime) greater than 20) + M(*) yields I2(A(sub 1u)) + M; and (3) I2(X;v(double prime) greater than 20) + M(*) yields 2I + M, where M(*) is I(2 P(1/2)) or O2(1 delta) and M is O2(3 Sigma) or I(2 P(3/2)). In the chain branching mechanism, initiation would involve near-resonant E-V transfer populating vibrational levels around v(double prime) = 40. Consequently, the relaxation dynamics of these levels are of interest as they may control the efficiency of the laser. The author examined the nascent state distribution of the I2(X) product using pulsed laser photolysis and probe techniques. In these experiments, I(2 P(1/2)) was generated by 496 nm photolysis of I2. Within several microseconds after the photolysis laser, I2(X;23 less than v(double prime) less than 47) is detected by laser excitation of the D-X transition at wavelengths in the 280-300 nm range. Rotationally-resolved spectra under single collision conditions were recorded for the D-X transitions 4 less than v(prime) less than 12 from 23 less than v(double prime) less than 47. Analysis of the data indicated that the molecular constants for the D state did not extrapolate to the v(prime) less than 30 levels reliably. In order to improve the characterization of the D state, a least-squares analysis generated improved spectroscopic constants. DTIC

LASER IONIZATION OF MOLECULAR CLUSTERS
S. Desai (Tennessee Univ., Knoxville, TN.), C. S. Feigerle (Tennessee Univ., Knoxville, TN.), and J. C. Miller 1995 5 p Presented at the 7th International Symposium on Resonance Ionization Spectroscopy and its Applications, Bernkastel-Kues, Germany, 3-8 Jul. 1994
(Contract DE-AC05-84OR-21400)
(DE95-007011; CONF-940706-2) Avail: CASI HC A01/MF A01

Multiphoton ionization coupled with mass spectrometry was used to investigate molecular cluster distributions. Three examples will be discussed in this presentation. First, in studies of neat nitric oxide clusters, (NO)(sub m), an interesting odd-even intensity alternation was observed and will be discussed in terms of electron-pairing considerations. In a separate study, the binary clusters comprising nitric oxide and methane preferentially form a stoichiometric cluster made up of repeating units of NO2CH4. These presumably represent a particularly strongly bound 'van der Waals' subunit. Finally, in similar studies of neat carbon disulfide clusters, (CS2)(sub m), additional photon absorption after the two-photon ionization step stimulates a series of intracluster ion-molecular reactions leading to formation of S(sub m)(sup +) and (CS)(sub m)(sup +) polymers, as well as intermediate species such as S(sub m)(sup +) (CS(sub 2)). This molecular cluster analogue of 'laser snow' will be described in detail. DOE

FREE ELECTRON LASER PHYSICAL PROCESS CODE (FELPPC)
L. E. Thode, K. C. D. Chan, and M. J. Schmitt 1995 12 p Presented at the SPIE '95: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract W-7405-eng-36)
(DE95-006276; LA-UR-95-339; CONF-950226-10) Avail: CASI HC A03/MF A01

Even at the conceptual level, the strong coupling between subsystem elements complicates the understanding and design of a free electron laser (FEL). Given the requirements for high-performance FELS, the coupling between subsystems must be included to obtain a realistic picture of the potential operational capability. The concept of an Integrated Numerical Experiment (INEX) was implemented to accurately calculate the coupling between the FEL subsystems. During the late 1980's, the INEX approach was successfully applied to a large number of accelerator and FEL experiments. Unfortunately, because of significant manpower and computational requirements, the integrated approach is difficult to apply to trade-off and initial design studies. However, the INEX codes provided a base from which realistic accelerator, wiggler, optics, and control models could be developed. The Free Electron Laser Physical Process Code (FELPPC) includes models developed from the INEX codes, provides coupling between the subsystem models, and incorporates application models relevant to a specific study. In other words, FELPPC solves the complete physical process model using realistic physics and technology constraints. FELPPC can calculate complex FEL configurations including multiple accelerator and wiggler combinations. When compared with the INEX codes, the subsystem models have been found to be quite accurate over many orders-of-magnitude. As a result, FELPPC has been used for the initial design studies of a large number of FEL applications: high-average-power ground, space, plane, and ship based FELS; beacon and illuminator FELS; medical and compact FELS; and XUV FELS. FEMTOSECOND X-RAY GENERATION THROUGH 90 DEGREES T HOMSON SCATTERING: STATUS OF THE LBL EXPERIMENT
W. Leemans, R. Schoenlein, A. Chin, E. Glover, M. Conde, S. Chattopadhyay, K. J. Kim, and C. V. Shank Nov. 1994 15 p Presented at the 6th Workshop on Advanced Accelerator Concepts, Lake Geneva, WI, 12-18 Jun. 1994
(Contract DE-AC03-76SF-00098)
(DE95-006560; LBL-36369; CBP-107; CONF-940681-9) Avail: CASI HC A03/MF A01

Scattering of femotosecond laser pulses off a low energy relativistic electron beam at 90 deg offers the possibility to generate ultrashort X ray pulses. Experiments are under preparation in the Beam Test Facility of the Center for Beam Physics at LBL to demonstrate the generation and detection of such pulses. The experiments involve a relativistic electron beam (tunable from 25-50 MeV) with a bunch length of 10 ps containing 1-2 nC, and an ultra short pulse (50-200 fs), high peak power (greater than 2 TW) 0.8 micrometers Ti:Al2O3 laser system. The electron beam, focused down to about a 50 micrometers waist size intersects the focused laser beam at 90 deg. The laser field acts as an electromagnetic undulator with strength K (quiver velocity of an electron normalized to the speed of light) for the relativistic electron beam, generating radiation up-shifted by 2(gamma)(sup 2)/(1+K(sup 2)/2) and a pulse length given by the overlapped interaction length in time of the laser beam and the electron beam. Here (gamma) is the usual Lorentz factor. Wavelength tuning will be accomplished in the experiment by generating wiggler strengths on the order of one as well as by electron beam energy tuning. For a 50 MeV electron beam and a laser beam focused to an intensity on the order of 10(exp 16) W/sq cm, the authors expect 10(exp 5) photons at 0.4 (angstrom) (10% bandwidth) in a cone angle of 6 mrad in a 170 fs pulse. DOE

LASER WITH OPTICALLY DRIVEN Q-SWITCH Patent
Hamid Hemmati, inventor (to NASA) (Jet Propulsion Lab., California Inst. of Tech., Pasadena, CA.) 18 Apr. 1995 5 p Filed 15 Jul. 1993 Supersedes N94-15932 (32 - 3, p 1038)
(Contract NAS7-918)
(NASA-Case-NPO-18470-1-CU; US-Patent-5,408,480; US-Patent-Appl-SN-094332; US-Patent-Class-372-10; US-Patent-Class-372-11; Int-Patent-Class-H01S-3/11) Avail: US Patent and Trademark Office

An optically driven interactive Q-switch, i.e., a Q-switch that responds to a short pulse of light, for example, from external light-emitting diodes (LED's) or diode lasers, is provided for producing an output laser pulse from electronic energy stored in a laser medium. Q-switching is thus achieved on demand by electrically pulsing the light source to produce a pulse of light directed onto a Q-switch medium in the laser cavity. Electronic control of the light pulse from the external source will thus provide not only efficient Q-switching frequency but also independent control of output laser pulse width with a fast rise time for each output laser pulse.

APPLICATION OF CONVENTIONAL LASER TECHNOLOGY TO GAMMA-GAMMA COLLIDERS
Christopher E. Clayton (California Univ., Los Angeles, CA.), Norman A. Kurnit, and David D. Meyerhofer (Rochester Univ., NY.) 1995 27 p Presented at the Workshop on Gamma-gamma Colliders, Berkeley, CA, 28-31 Mar. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract W-7405-eng-36)
(DE95-006341; LA-UR-95-34; CONF-940351-5) Avail: CASI HC A03

A future e(-)e(+) (electron-positron) linear collider can be configured with perhaps minimal modification to serve as a gamma-gamma or a e(-)-gamma collider. This is accomplished by Compton-backscattering low energy photons (from a laser source) off of the high-energy electron beams prior to the crossing of the electron beams. However, to be competitive with the e(-)e(+) configuration, the luminosity cannot be compromised in the process. This requires that the laser source deliver a sufficient number of photons per pulse with a pulse format and rate matching that of the electron beams. As it turns out, this requires an average optical power of 5 to 15 kW from the laser which is beyond the current state of the art. In this paper, the authors address how to generate the required pulse format and how the high average power requirement can be met with conventional laser technology. They also address concerns about the survivability of mirrors located near the interaction point. Finally, they list a program of research and development which addresses some of the unknowns in such a system. DOE

TIME-DEPENDENT MULTI-DIMENSIONAL SIMULATION STUDIES OF THE ELECTRON OUTPUT SCHEME FOR HIGH POWER FELS
S. J. Hahn, W. M. Fawley, K. J. Kim, and J. A. Edighoffer Dec. 1994 4 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract DE-AC03-76SF-00098)
(DE95-006593; LBL-35534; CONF-9408146-18) Avail: CASI HC A01/MF A01

The authors examine the performance of the so-called electron output scheme recently proposed by the Novosibirsk group. In this scheme, the key role of the FEL oscillator is to induce bunching, while an external undulator, called the radiator, then outcouples the bunched electron beam to optical energy via coherent emission. The level of the intracavity power in the oscillator is kept low by employing a transverse optical klystron (TOK) configuration, thus avoiding excessive thermal loading on the cavity mirrors. Time-dependent effects are important in the operation of the electron output scheme because high gain in the TOK oscillator leads to sideband instabilities and chaotic behavior. The authors have carried out an extensive simulation study by using 1D and 2D time-dependent codes and find that proper control of the oscillator cavity detuning and cavity loss results in high output bunching with a narrow spectral bandwidth. Large cavity detuning in the oscillator and tapering of the radiator undulator is necessary for the optimum output power. DOE

TRIDENT AS AN ULTRAHIGH IRRADIANCE LASER
R. P. Johnson, N. K. Moncur, J. A. Cobble, R. G. Watt, and R. B. Gibson 1995 10 p Presented at the SPIE '95: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract W-7405-eng-36)
(DE95-006345; LA-UR-95-41; CONF-950226-8) Avail: CASI HC A02/MF A01

The Trident Nd:glass ICF laser at Los Alamos may be operated in a mode that produces high ultrashort pulses by the chirp/compression method. The 125-ps pulses from a standard moderated, Nd:YLF oscillator are first frequency-broadened to 3-nm bandwidth, chirped in a quartz fiber, and then compressed with a grating pair to 1.5 ps. A second quartz fiber then provides nonlinear polarization rotation for background and satellite suppression and to further broaden the spectrum to greater than 7 nm. Pulses are chirped again to 1 ns width with a second grating pair and amplified in a ND:YAG pumped Ti:sapphire regenerative amplifier. Millijoule-level output is then amplified through the existing phosphate glass Trident amplifier chain before compression to less than 400 fs. Energy greater than or equal to 1 J with excellent beam quality and contrast ratio is routinely produced by compressing after three rod amplifier stages. Higher energies are possible by compression further along the amplifier chain. Simultaneous use of long (approximately 1 ns) pulses for plasma formation is also possible. DOE

Far-infrared laser interferometry at 432 micro m was carried out on the STP-3(M) reversed-field pinch. Measurements along two vertical chords showed a change from a parabolic-like to a flat-like electron density profile after field reversal. A density profile inversion and a correlated toroidal magnetic flux perturbation were also observed during the transition from the current rising to the current decay phase. Measurements of electron density fluctuations indicated relative fluctuation levels of approx. 10% for both chords during the current rising phase and approx. 5% and approx. 15% during the current decay phase for the central and outer chords, respectively. Spectral analysis showed a approx. 30 kHz mode consistent with poloidal mode number m = 0 magnetic fluctuations, and a approx. 90 kHz mode localized to the outer region of the plasma, which was strongly excited during the current decay phase and may be connected to particle and energy transport in STP-3(M). DOE

TIME-DEPENDENT MODEL FOR VERTICAL-CAVITY SURFACE-EMITTING LASER
L. Thode, G. Csanak, R. Hotchkiss, and C. Snell 1995 13 p Presented at the SPIE 1995: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract W-7405-eng-36)
(DE95-007880; LA-UR-95-534; CONF-950226-23) Avail: CASI HC A03/MF A01

Two models have been developed to simulate a vertical-cavity surface-emitting laser (VCSEL). The first model is a two-dimensional time-dependent solution of Maxwell's equations, with frequency-independent bulk dielectric and absorption coefficients. These bulk coefficients depend upon the material, lattice temperature, and carrier concentration. This field model is coupled with a frequency-dependent gain model that describes the quantum well regions in the time domain. Treatment of frequency-dependent media in a finite-difference time-domain code is computationally intensive. On the other hand, because the volume of the active region is small relative to the volume of the distributed laser cavity, the computational overhead is reasonable. A semi-empirical transport model is used to describe the bulk transport, which drives the quantum well transport. In addition, the semi-empirical model provides a spatial distribution for the lattice temperature and carrier concentrations. The second model is a three-dimensional solution of Maxwell's equations. The three-dimensional model can be used for cold-cavity calculations. The two-dimensional code generates the dielectric and absorption coefficients assuming azimuthal symmetry, providing the initial conditions for the three-dimensional calculation. DOE

HIGH POWER FREE-ELECTRON LASER CONCEPTS AND PROBLEMS
J. C. Goldstein 1995 14 p Presented at the SPIE '95: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract W-7405-eng-36)
(DE95-007841; LA-UR-95-830; CONF-950226-17) Avail: CASI HC A03/MF A01

Free-electron lasers (FEL's) have long been thought to offer the potential of high average power operation. That potential exists because of several unique properties of FEL's, such as the removal of 'waste heat' at the velocity of light, the 'laser medium' (the electron beam) is impervious to damage by very high optical intensitites, and the technology of generating very high average power relativistic electron beams. In particular, if one can build a laser with a power extraction efficiency 11 which is driven by an electron beam of average Power P(sub EB), one expects a laser output power of P(sub L) = eta P(sub EB). One approach to FEL devices with large values of eta (in excess of 10%) is to use a 'tapered' (or nonuniform) wiggler. This approach was followed at several laboratories during the FEL development Program for the Strategic Defense Initiative (SDI) project. In this paper, we review some concepts and technical requirements for high-power tapered-wiggler FELs driven by radio-frequency linear accelerators (RF-linacs) which were developed during the SDI project. Contributions from three quite different technologies - RF-accelerators, optics, and magnets - are needed to construct and operate an FEL oscillator. The particular requirements on these technologies for a high-power FEL were far beyond the state of the art in those areas when the SDI project started, so significant advances had to be made before a working device could be constructed. Many of those requirements were not clearly understood when the project started, but were developed during the course of the experimental and theoretical research for the project. This information can be useful in planning future high-power FEL projects. DOE

FINITE PULSE EFFECTS IN SELF-AMPLIFIED-SPONTANEOUS EMISSION
Kwang-Je Kim and Sang June Hahn Sep. 1994 10 p Presented at the 16th International Free Electron Laser Conference, Stanford, CA, 21-26 Aug. 1994
(Contract DE-AC03-76SF-00098)
(DE95-006585; LBL-36582; CONF-9408146-15) Avail: CASI HC A02/MF A01

The authors study the effects of the electron density profile on self amplified spontaneous emission (SASE). A general formalism in the linear regime is developed by deriving the coupled Maxwell-Klimontovich equations for an arbitrary density profile and including the effects of the energy spread, diffraction, and the betatron oscillation. An explicit solution is obtained for the one-dimensional (1-D) case. The temporal and the spectral intensity profiles of SASE depend linearly on the initial electron correlation function. The correlation function consists of two terms, a term giving rise to the usual spontaneous radiation and its amplification to SASE, and a term representing the coherent bunched beam effect. The latter term has been neglected so far in the treatments of SASE, but it could be significant when there is a variation in the electron density at a length scale comparable to the wavelength. The theory reproduces the well-known results when the electron density is uniform. It also reproduces a recent theory for a finite top-hat density profile and a vanishing energy spread. DOE

PULSED LASER DEPOSITION OF ZEOLITIC MEMBRANES
N. M. Peachey, R. C. Dye, and P. D. Ries (Dow Chemical Co., Midland, MI.) 1995 8 p Presented at the 17th International Conference on Lasers and Applicators, Qubec, Canada, 12-14 Dec. 1994
(Contract W-7405-eng-36)
(DE95-006274; LA-UR-95-342; CONF-941259-1) Avail: CASI HC A02/MF A01

The pulsed laser deposition of zeolites to form zeolitic thin films is described. Films were grown using both mordenite and faujasite targets and were deposited on various substrates. The optimal films were obtained when the target and substrate were separated by 5 cm. These films are comprised of small crystallites embedded in an amorphous matrix. Transmission electron microscopy reveals that the amorphous material is largely porous and that the pores appear to be close to the same size as the parent zeolite. Zeolotic thin films are of interest for sensor, gas separation, and catalytic applications. DOE

SURFACE-EMITTING SEMICONDUCTOR LASER FOR INTRACAVITY SPECTROSCOPY AND MICROSCOPY
K. E. Meissner, P. L. Gourley, T. M. Brennan, B. E. Hammons, and A. E. McDonald 1995 10 p Presented at the SPIE 1995: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-007745; SAND-95-0162C; CONF-950226-13) Avail: CASI HC A02/MF A01

The authors demonstrate lasing action in a novel microcavity laser which can be utilized for intracavity spectroscopy as well as high contrast imaging of small (approximately 10(mu)m) structures. The system can be easily visualized as a Fabry-Perot cavity containing a gain media and an object for study. Since the primary constraint on the object is transparency at the lasing wavelength, investigation of lasing in objects such as microspheres, liquid droplets, and biological cells is possible. The resonator consists of an epitaxial NME grown mirror and gain region on a GaAs wafer. This is essentially an open-cavity vertical cavity surface emitting laser (VCSEL). The object to be studied is placed on the wafer and covered with a glass dielectric mirror which acts as the output coupler. When the semiconductor gain region is photo-pumped, the object within the cavity provides lateral optical confinement through its index difference with the surrounding media, increases the cavity Q, and thus encourages lasing action. The emitted laser light can be spectrally and spatially resolved. The narrow lasing lines can provide information about the lasing modes supported and the size of the object. The spatially resolved laser light provides high contrast microscopic images of the electromagnetic modes oscillating in the resonator. The authors present an investigation of stable lasing modes in polystyrene spheres. This device could prove useful in biomedical diagnostics. It covers the correct spatial dimensions as well as wavelength region. In fact, an integrated system of these devices may provide a high speed, compact method of performing cell diagnostics. DOE

COMPREHENSIVE NUMERICAL MODEL FOR CW VERTICAL-CAVITY SURFACE-EMITTING LASERS
G. R. Hadley, K. L. Lear, M. E. Warren, K. D. Choquette, J. W. Scott (Optical Concepts, Inc., Lompoc, CA.), and S. W. Corzine (California Univ., Santa Barbara, CA.) 1995 12 p Presented at the SPIE 1995: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-007758; SAND-95-0274C; CONF-950226-14) Avail: CASI HC A03/MF A01

The authors present a comprehensive numerical model for vertical-cavity surface-emitting lasers that includes all major processes effecting CW operation of axisymmetric devices. In particular, the model includes a description of the 2D transport of electrons and holes through the cladding layers to the quantum well(s), diffusion and recombination processes of these carriers within the wells, the 2D transport of heat throughout the device, and a multi-lateral-mode effective index optical model. The optical gain acquired by photons traversing the quantum wells is computed including the effects of strained band structure and quantum confinement. They employ the model to predict the behavior of higher-order lateral modes in proton-implanted devices, and to provide an understanding of index-guiding in devices fabricated using selective oxidation. Extreme UltraViolet Lithography (EUVL) seeks to apply radiation in a wavelength region centered near 13 nm to produce microcircuits having features sizes 0.1 micron or less. A critical requirement for the commercial application of this technology is the development of an economical, compact source of this radiation which is suitable for lithographic applications. A good candidate is a laser-plasma source, which is generated by the interaction of an intermediate intensity laser pulse (up to 10(exp 12) W/sq cm) with a metallic target. While such a source has radiative characteristics which satisfy the needs of an EUVL source, the debris generated during the laser-target interaction strikes at the economy of the source. Here, the authors review the use of concepts and computer modeling, originally developed for hypervelocity impact analysis, to study this problem. DOE

APPLICATIONS OF LASERS AND ELECTRO-OPTICS
B. C. Tan, K. S. Low, Y. H. Chen, Harith Ahmad, and T. Y. Tou 1994 16 p Presented at the National Seminar on the Assessment of IRPA Research Achievement in 5th Malaysian Plan: Industrial Sector, Kedah, Malaysia, 20-24 Dec. 1991
(DE95-600841; INIS-mf-14339; CONF-9112185) Avail: CASI HC A03/MF A01 (US Sales Only)

Supported by the IRPA Programme on Laser Technology and Applications, many types of lasers have been designed, constructed and applied in various areas of science, medicine and industries. Amongst these lasers constructed were high power carbon dioxide lasers, rare gas halide excimer lasers, solid state Neodymium-YAG lasers, nitrogen lasers, flashlamp pumped dye lasers and nitrogen and excimer laser pumped dye lasers. These lasers and the associated electro-optics system, some with computer controlled, are designed and developed for the following areas of applications: (1) industrial applications of high power carbon dioxide lasers for making of i.c. components and other materials processing purposes -- prototype operational systems have been developed; (2) Medical applications of lasers for cancer treatment using the technique of photodynamic therapy -- a new and more effective treatment protocol has been proposed; (3) agricultural applications of lasers in palm oil and palm fruit-fluorescence diagnostic studies -- fruit ripeness signature has been developed and palm oil oxidation level were investigated; (4) development of atmospheric pollution monitoring systems using laser lidar techniques -- laboratory scale systems were developed; and (5) other applications of lasers including laser holographic and interferometric methods for the non destructive testing of materials. CHARACTERIZATION OF SOLID STATE LASER AND NONLINEAR OPTICAL MATERIALS Final Report, 12 Apr. 1991 - 30 Jun. 1994
Jin-Joo Song 2 Feb. 1995 288 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-91-G-0099)
(AD-A291684; ARO-28472.11-PH) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Optical properties of materials having applications in solid state laser systems were investigated. The work was divided into two areas based on the materials useful in the different methods for obtaining frequency agility: narrow line emitters with multiple lasing channels and nonlinear optical materials. In the first category the spectral dynamics and lasing properties of a variety of materials such as fluoride and oxide crystals and glasses codoped with two or more rare-earth ions were studied and computers models developed to explain their spectral dynamics. The nonlinear optical materials investigated included rare-earth doped glasses, photorefractive crystals, and semiconductors. Laser spectroscopy techniques used to characterize these materials included four-wave mixing, two photon absorption and fluorescence line narrowing. The results were related to laser device parameters in order to determine the basic physical processes in the operational device parameters. DTIC

Recently several techniques have become available to measure the time- (or frequency-) dependent intensity and phase of ultrashort laser pulses. One of these, Frequency-Resolved Optical Gating (FROG), is rigorous and has achieved single-laser-shot operation. FROG combines the concepts of time-frequency analysis in the form of spectrogram generation (in order to create a two-dimensional problem), and uses a phase-retrieval-based algorithm to invert the experimental data to yield the intensity and phase of the laboratory laser pulse. In FROG it is easy to generate a spectrogram of the unknown signal, and inversion of the spectrogram to recover the signal is the main goal. Because the temporal width of a femtosecond laser pulse is much shorter than anything achievable by electronics, FROG uses the pulse to measure itself. In FROG, the laser pulse is split into two replicas of itself by a partially reflecting beamsplitter, and the two replicas interact with each other in a medium with an instantaneous nonlinear-optical response. This interaction generates a signal field that is then frequency-resolved using a spectrometer. The spectrum of the signal field is measured for all relevant values of the temporal delay between the two pulses. Here, the authors employ FROG and FROG related techniques to measure the time-dependent intensity and phase of an ultrashort laser pulse. DOE

VALVE MECHANISM FOR AN ACOUSTIC MODULATOR Patent
James L. Sullivan, inventor (to Navy) and Gary S. Borgen, inventor (to Navy) 27 Sep. 1994 12 p Filed 23 Aug. 1993
(AD-D017263; US-Patent-5,349,986; US-Patent-Appl-SN-112814) Avail: US Patent and Trademark Office

A valve mechanism for an acoustic modulator which modulates air flowing through the acoustic modulator. The valve mechanism comprises a pair of cylindrical shaped members with each member having a plurality of elongated ports. The first cylindrical shaped member is held in a fixed position, while the second cylindrical shaped member is movable with respect to the first member. There is located at the lower end of the second cylindrical shaped member a drive coil which is positioned in a magnetic field such that when the coil is excited by an electrical sinusoidal input signal, movement of the second member occurs, partially aligning the ports of the second member with the ports of the first member which opens the valve mechanism. The sinusoidal input signal causes a frequency 'doubling' to occur, that is the valve mechanism of the present invention completes an open-close-open-close cycle during each cycle of the sinusoidal input signal. This frequency 'doubling' modulation of air flow through the acoustic modulator is accomplished by exposing the same open port area for both the positive going portion and the negative going portion of the sinusoidal input signal. The valve mechanism 'closes' when the sinusoidal input signal is at zero volts. DTIC

(NASA-TM-106585; E-9473; NAS 1.15:106585) Avail: CASI HC A03/MF A01

Nearly five decades have passed since G. Lundberg and A. Palmgren published their life theory in 1947 and 1952 and it was adopted as an ANSI/ABMA and ISO standard in 1950 and 1953. Subsequently, many variations and deviations from their life theory have been proposed, the most recent being that of E. Ioannides and T.A. Harris in 1985. This paper presents a critical analysis comparing the results of different life theories and discussing their implications in the design and analysis of rolling-element bearings. Variations in the stress-life relation and in the critical stress related to bearing life are discussed using stress fields obtained from three-dimensional, finite-element analysis of a ball in a nonconforming race under varying load. The results showed that for a ninth power stress-life exponent the Lundberg-Palmgren theory best predicts life as exhibited by most air-melted bearing steels. For a 12th power relation reflected by modern bearing steels, a Zaretsky-modified Weibull equation is superior. The assumption of a fatigue-limiting stress distorts the stress-life exponent and overpredicts life. Author

A SYSTEMS ENGINEERING APPROACH TO ELECTRO-MECHANICAL RECONFIGURATION FOR MOBILITY AUTONOMY

R. C. Coulter 15 Aug. 1994 48 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contracts DAAE07-90-C-R059; DACA76-89-C-0014)

(AD-A289479; CMU-RI-TR-94-27) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The performance of a system is a function of the performance of each of its individual components. This work explores the relationship between system performance and subcomponent performance in the electro-mechanical configuration of a mobile robot under the premise that the performance of the mobile robot can be greatly improved through the systematic analysis and design of an efficient electro-mechanical configuration. This work further presumes that the concept of mobility adequately encompasses the metrics by which complete mobile robotic systems may be measured; the purpose of building a mobile robot is assumed to be the creation of a maximally mobile autonomous machine. The performance cost of converting an existing machine into an autonomous machine is then measured by its mobility degradation. DTIC

DYNAMIC COUPLING OF UNDERACTUATED MANIPULATORS Research Report

Marcel Bergerman, Christopher Lee, and Yangsheng Xu Aug. 1994 36 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289404; CMU-RI-TR-94-25) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In recent years, researchers have been turning their attention to so called underactuated systems, where the term underactuated refers to the fact that the system has more joints than control actuators. Some examples of underactuated systems are robot manipulators with failed actuators; free-floating space robots, where the base can be considered as a virtual passive linkage in inertia space; legged robots with passive joints; hyper-redundant (snake-like) robots with passive joints, etc. From the examples above, it is possible to justify the importance of the study of underactuated systems. For example, if some actuators of a conventional manipulator fail, the loss of one or more degrees of freedom may compromise an entire operation. In free-floating space systems, the base (satellite) can be considered as a 6-DOF device without positioning actuators. Finally, manipulators with passive joints and hyper-redundant robots with few actuators are important from the viewpoint of energy saving, lightweight design and compactness. DTIC

EFFECT OF HOOP STRESS ON BALL BEARING LIFE PREDICTION

Erwin V. Zaretsky, Richard August (NYMA, Inc., Brook Park, OH.), and Harold H. Coe May 1995 21 p Presented for Annual Meeting, Chicago, IL, 14-19 May 1995; sponsored by the Society of Tribologists and Lubrication Engineers

(RTOP 505-63-5B)

(NASA-TM-106874; E-9497; NAS 1.15:106874) Avail: CASI HC A03/MF A01

A finite-element analysis (FEA) of a generic, dimensionally normalized inner race of an angular-contact ball bearing was performed under varying conditions of speed and the press (or interference) fit of the inner-race bore on a journal. The FEA results at the ball-race contact were used to derive an equation from which was obtained the radius of an equivalent cylindrical bearing race with the same or similar hoop stress. The radius of the equivalent cylinder was used to obtain a generalized closed-form approximation of the hoop stresses at the ball-inner-race contact in an angular-contact ball bearing. A life analysis was performed on both a 45- and a 120-mm-bore, angular-contact ball bearing. The predicted lives with and without hoop stress were compared with experimental endurance results obtained at 12000 and 25000 rpm with the 120-mm-bore ball bearing. A life factor equation based on hoop stress is presented. Author

SXI PROTOTYPE MIRROR MOUNT Final Report

Apr. 1995 81 p

(Contract NAS8-38609)

(NASA-CR-196613; NAS 1.26:196613) Avail: CASI HC A05/MF A01

This final report describes the work performed from June 1993 to January 1995. The purpose of this contract was to provide optomechanical engineering and fabrication support to the Solar X-ray Imager (SXI) program in the areas of mirror, optical bench and camera assemblies of the telescope. The Center for Applied Optics (CAO) worked closely with the Optics and S&E technical staff of MSFC to develop and investigate the most viable and economical options for the design and fabrication of a number of parts for the various telescope assemblies. All the tasks under this delivery order have been successfully completed within budget and schedule. Author (revised)

DIAGNOSIS OF HELICOPTER GEARBOXES USING STRUCTURE-BASED NETWORKS
Vinay B. Jammu (Massachusetts Univ., Amherst, MA.), Kourosh Danai (Massachusetts Univ., Amherst, MA.), and David G. Lewicki (Army Research Lab., Cleveland, OH.) Jun. 1995 7 p Presented at the Symposium on Applied Monitoring and Diagnositics, Seattle, WA, 21-23 Jul. 1995; sponsored by American Automatic Control Council
(RTOP 505-62-36; DA Proj. 1L1-62211-A-47-A)
(NASA-TM-106932; E-9659; NAS 1.15:106932; ARL-TR-761) Avail: CASI HC A02/MF A01

A connectionist network is introduced for fault diagnosis of helicopter gearboxes that incorporates knowledge of the gearbox structure and characteristics of the vibration features as its fuzzy weights. Diagnosis is performed by propagating the abnormal features of vibration measurements through this Structure-Based Connectionist Network (SBCN), the outputs of which represent the fault possibility values for individual components of the gearbox. The performance of this network is evaluated by applying it to experimental vibration data from an OH-58A helicopter gearbox. The diagnostic results indicate that the network performance is comparable to those obtained from supervised pattern classification. Author

ADVANCES IN WELDING SCIENCE: A PERSPECTIVE
S. A. David, J. M. Vitek, S. S. Babu (Pennsylvania State Univ., University Park, PA.), and T. DebRoy (Pennsylvania State Univ., University Park, PA.) 1995 23 p Presented at the Welding Technology Institute of Australia (WTIA) Annual Conference, Melbourne, Australia, 24-27 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE95-006745; CONF-9410296-1) Avail: CASI HC A03/MF A01

The ultimate goal of welding technology is to improve the joint integrity and increase productivity. Over the years, welding has been more of an art than a science, but in the last few decades major advances have taken place in welding science and technology. With the development of new methodologies at the crossroads of basic and applied sciences, enormous opportunities and potential exist to develop a science-based tailoring of composition, structure, and properties of welds with intelligent control and automation of the welding processes. USING HOB OFFSET TO BALANCE DYNAMIC STRENGTH IN SPUR GEARS
Chuen-Huei Liou (Memphis Univ., Memphis, TN.), Hsi Hsiang Lin (Memphis Univ., Memphis, TN.), Fred B. Oswald, and Dennis P. Townsend May 1995 11 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE
(RTOP 505-62-36; DA Proj. 1L1-62211-A-47-A)
(NASA-TM-106934; E-9661; NAS 1.15:106934; ARL-TR-764; AIAA Paper 95-3046) Avail: CASI HC A03/MF A01

This paper presents an analytical study on the effect of hob offset on the dynamic tooth strength of spur gears. The study was limited to equal and opposite offset values applied to the pinion and gear to maintain the standard operating center distance. The analysis presented in this paper was performed using a new version of the NASA gear dynamics code DANST. The operating speed of the transmission has a significant influence on the amount of hob offset required to equalize the dynamic stresses in the pinion and gear. In the transmission studied, at low speeds, the optimum hob offset value was found to fluctuate. At higher speeds, the optimum value was constrained by the minimum allowed thickness at the tip of the pinion tooth. For gears that must operate over a range of speeds, an average offset value may be used. Spur gears designed with the procedure presented here can have significant improvements in load capacity. THE VIBRATION TRANSMISSION OF LIFT TRUCK SUSPENSION SEATS
Xuting Wu, Michael J. Griffin, and Christopher H. Lewis Apr. 1995 41 p
(ISVR-TR-245) Copyright Avail: Issuing Activity (Southampton Univ., Southampton, England)

The vibration isolation efficiencies of three suspension seats have been measured according to a draft standard for the vibration transmitted by the seats of lift trucks. The vertical vibration transmission ratios were measured with spectra corresponding to the z-axis motions of two classes of lift truck. The results of the measurements on each seat are presented in appendices. The effect of subject weight is discussed and the 50th percentile subject weight is suggested to replace the 55 (+0 to -3) kg and 98 (+5 to -0) kg subject weight recommended in the draft. End-stop impacts may be an important problem with real vehicle motion. It is suggested that a method of testing for end-stop impacts should be included in the standard. Author

VIBRATION ANALYSIS OF A SPLIT PATH GEARBOX
Timothy L. Krantz and Majid Rashidi (Cleveland State Univ., OH.) May 1995 15 p Presented at the 31st Joint Propulsion Conference, San Diego, CA, 10-12 Jul. 1995; cosponsored by AIAA, SAE, and ASME
(RTOP 505-62-36; DA Proj. 1L1-62211-A-47-A)
(NASA-TM-106875; E-9498; NAS 1.15:106875; ARL-TR-723; AIAA Paper 95-3048) Avail: CASI HC A03/MF A01

Split path gearboxes can be attractive alternatives to the common planetary designs for rotorcraft, but because they have seen little use, they are relatively high risk designs. To help reduce the risk of fielding a rotorcraft with a split path gearbox, the vibration and dynamic characteristics of such a gearbox were studied. A mathematical model was developed by using the Lagrangian method, and it was applied to study the effect of three design variables on the natural frequencies and vibration energy of the gearbox. The first design variable, shaft angle, had little influence on the natural frequencies. The second variable, mesh phasing, had a strong effect on the levels of vibration energy, with phase angles of 0 deg and 180 deg producing low vibration levels. The third design variable, the stiffness of the shafts connecting the spur gears to the helical pinions, strongly influenced the natural frequencies of some of the vibration modes, including two of the dominant modes. We found that, to achieve the lowest level of vibration energy, the natural frequencies of these two dominant modes should be less than those of the main excitation sources. Author

(Contracts DE-AC05-84OR-21400; DE-AC03-89ER-51114)
(DE95-007049; CONF-941001-11; CONF-9410295-1) Avail: CASI HC A03/MF A01

The He ash generated as a result of D/T burn in a fusion reactor must be exhausted from the plasma to avoid fuel dilution effects. In view of this, transport and exhaust studies of He in fusion plasmas are getting increasing attention in recent years. In fusion plasmas, the exhaust gas will be a combination of D2 and He, with He forming only a small fraction (about 10%). The authors have investigated the cryosorption pumping characteristics of pure He and a mixture of D2 and He (90% D2) using a cryosorption pump with condensed layers of Ar as sorbent. A cryocondensation pump cooled by liquid He at 4.3 K, and located in the outboard divertor region of the DIII-D tokamak, was used for the experiment. The investigation was conducted in a pressure regime that is relevant for particle exhaust from fusion plasmas. The experiment revealed that: (1) cryosorption pumping speed of pure He drops precipitously if the Ar/He ratio falls below about 20; (2) the pumping speed for He in a D2/He mixture decreases in an exponential manner with the amount of D2 pumped; (3) increasing the thickness of Ar in the range of 1 - 12 micro m had little effect on the pumping speed for He in a D2/He mixture; and (4) for a pumping surface coated with a thick (greater than 2 micro m)layer of Ar, surrounded by a radiation shield having a transparency factor of about 6, a He pumping speed in the range of 15-25 cu m/s sq m, in the millitorr pressure range for pulse duration of about 5 s can be obtained after pumping about 80 torr 1 of D2. SYSTEM IDENTIFICATION OF DAMPED TRUSS-LIKE SPACE STRUCTURES Ph.D. Thesis - Cleveland State Univ., Mar. 1994
Sasan Armand May 1995 281 p
(RTOP 505-69-50)
(NASA-TM-106638; E-8941; NAS 1.15:106638) Avail: CASI HC A13/MF A03

A spacecraft payload flown on a launch vehicle experiences dynamic loads. The dynamic loads are caused by various phenomena ranging from the start-up of the launch vehicle engine to wind gusts. A spacecraft payload should be designed to meet launch vehicle dynamic loads. One of the major steps taken towards determining the dynamic loads is to correlate the finite element model of the spacecraft with the test results of a modal survey test. A test-verified finite element model of the spacecraft should possess the same spatial properties (stiffness, mass, and damping) and modal properties (frequencies and mode shapes) as the test hardware representing the spacecraft. The test-verified and correlated finite element model of the spacecraft is then coupled with the finite element model of the launch vehicle for analysis of loads and stress. Modal survey testing, verification of a finite element model, and modification of the finite element model to match the modal survey test results can easily be accomplished if the spacecraft structure is simple. However, this is rarely the case. A simple structure here is defined as a structure where the influence of nonlinearity between force and displacement (uncertainty in a test, for example, with errors in input and output), and the influence of damping (structural, coulomb, and viscous) are not pronounced. The objective of this study is to develop system identification and correlation methods with the focus on the structural systems that possess nonproportional damping. Two approaches to correct the nonproportional damping matrix of a truss structure were studied, and have been implemented on truss-like structures such as the National Aeronautics and Space Administration's space station truss. The results of this study showed nearly 100 percent improvement of the correlated eigensystem over the analytical eigensystem. The first method showed excellent results with up to three modes used in the system identification process. The second method could handle more modes, but required more computer usage time, and the results were less accurate than those of the first method. Author

ANALYTICAL AND EXPERIMENTAL EVALUATION OF JOINING SILICON CARBIDE TO SILICON CARBIDE AND SILICON NITRIDE TO SILICON NITRIDE FOR ADVANCED HEAT ENGINE APPLICATIONS, PHASE 2 Final Report
G. J. Sundberg, A. M. Vartabedian, J. A. Wade, and C. S. White Oct. 1994 122 p
(Contract DE-AC05-84OR-21400)
(DE95-005761; ORNL/Sub-87-SB045/2) Avail: CASI HC A06/MF A02

The purpose of joining, Phase 2 was to develop joining technologies for HIP'ed Si3N4 with 4wt% Y2O3 (NCX-5101) and for a siliconized SiC (NT230) for various geometries including: butt joins, curved joins and shaft to disk joins. In addition, more extensive mechanical characterization of silicon nitride joins to enhance the predictive capabilities of the analytical/numerical models for structural components in advanced heat engines was provided. Mechanical evaluation were performed by: flexure strength at 22 C and 1,370 C, stress rupture at 1,370 C, high temperature creep, 22 C tensile testing and spin tests. While the silicon nitride joins were produced with sufficient integrity for many applications, the lower join strength would limit its use in the more severe structural applications. Thus, the silicon carbide join quality was deemed unsatisfactory to advance to more complex, curved geometries. The silicon carbide joining methods covered within this contract, although not entirely successful, have emphasized the need to focus future efforts upon ways to obtain a homogeneous, well sintered parent/join interface prior to siliconization. In conclusion, the improved definition of the silicon carbide joining problem obtained by efforts during this contract have provided avenues for future work that could successfully obtain heat engine quality joins. A HYBRID VEHICLE EVALUATION CODE AND ITS APPLICATION TO VEHICLE DESIGN. REVISION 1
S. M. Aceves and J. R. Smith 15 Sep. 1994 26 p Presented at the Society of Automotive Engineers International Congress and Exposition, Detroit, MI, 27 Feb. - 2 Mar. 1995
(Contract W-7405-eng-48)
(DE95-008053; UCRL-JC-117918-Rev-1; CONF-950256-1) Avail: CASI HC A03/MF A01

This paper describes a hybrid vehicle simulation model which can be applied to many of the vehicles currently being considered for low pollution and high fuel economy. The code operates in batch mode with all the vehicle information stored in data files. The code calculates fuel economy for three driving schedules, time for 0-96 km/h at maximum acceleration, hill climbing performance, power train dimensions, and pollution generation rates. This paper also documents the application of the code to a hybrid vehicle that utilizes a hydrogen internal combustion engine. The simulation model is used for parametric studies of the vehicle. The results show the fuel economy of the vehicle as a function of vehicle mass, aerodynamic drag, engine efficiency, accessory load, and flywheel efficiency. The code also calculates the minimum flywheel energy and power to obtain a desired performance. The hydrogen hybrid vehicle analyzed in the paper has a predicted range of 480 km (300 miles), with a gasoline equivalent fuel efficiency of 34.2 km/liter (80.9 mpg). DOE

(Contract W-31-109-eng-38)
(DE95-008275; ANL/ITD/CP-85767) Avail: CASI HC A03/MF A01

Argonne National Laboratory is a multiprogram research and development laboratory operated by The University of Chicago for the US Department of Energy. At Argonne, applied research in thermal and mechanical sciences is performed within the Thermal and Mechanical Sciences Section of the Energy Technology Division. Current program areas include compact evaporators and condensers for the process and transportation industries, ice slurries for district cooling, advanced fluids for improved heat transfer and reduced pressure drop, flow-induced vibration and flow distribution in shell-and-tube heat exchangers, and dynamics and control of maglev systems. In general, the objective of the research is to extend the technology base in each of these areas and to facilitate its application in solving problems of importance to US industries and utilities. This is accomplished by developing validated design correlations and predictive methods. The staff of the Thermal and Mechanical Sciences Section have extensive experimental and analytical experience in heat transfer, multiphase flow, structural dynamics and control, fluid-structure interaction, transient flow and mixing, thermally driven flows, and flow visualization using ultra-high-speed video. Large, general-purpose test facilities and smaller, single-purpose test apparatuses are available for experiments and component design evaluation. A world-class capability in the study of flow-induced vibrations exists within the section. Individual fact sheets, describing currently active research program areas and related facilities and listing, as a contact, the principal investigator, are included. DOE

Int-Patent-Class-F02M-65/00) Avail: US Patent and Trademark Office

An apparatus for testing and evaluating the spray pattern of high pressure fuel injector elements for use in supplying fuel to combustion engines is presented. Prior art fuel injector elements were normally tested by use of low pressure apparatuses which did not provide a purge to prevent mist from obscuring the injector element or to prevent frosting of the view windows; could utilize only one fluid during each test; and had their viewing ports positioned one hundred eighty (180 deg) apart, thus preventing optimum use of laser diagnostics. The high pressure fluid injector test apparatus includes an upper hub, an upper weldment or housing, a first clamp and stud/nut assembly for securing the upper hub to the upper weldment, a standoff assembly within the upper weldment, a pair of window housings having view glasses within the upper weldment, an injector block assembly and purge plate within the upper weldment for holding an injector element to be tested and evaluated, a lower weldment or housing, a second clamp and stud/nut assembly for securing the lower weldment to the upper hub, a third clamp and stud/nut assembly for securing the lower hub to the lower weldment, mechanisms for introducing fluid under high pressure for testing an injector element, and mechanisms for purging the apparatus to prevent frosting of view glasses within the window housings and to permit unobstructed viewing of the injector element.

WATER DRIVEN TURBINE/BRUSH PIPE CLEANER Patent
Rudy J. Werlink, inventor (to NASA) 18 Apr. 1995 8 p Filed 7 Mar. 1994
(NASA-Case-KSC-11669-1; US-Patent-5,406,666;
US-Patent-Appl-SN-207313; US-Patent-Class-15-104.12;
US-Patent-Class-15-104.31; Int-Patent-Class-B08B-9/02) Avail: US Patent and Trademark Office

Assemblies are disclosed for cleaning the inside walls of pipes and tubes. A first embodiment includes a small turbine with angled blades axially mounted on one end of a standoff support. An O-ring for stabilizing the assembly within the pipe is mounted in a groove within the outer ring. A replaceable circular brush is fixedly mounted on the opposite end of the standoff support and can be used for cleaning tubes and pipes of various diameters, lengths and configurations. The turbine, standoff support, and brush spin in unison relative to a hub bearing that is fixedly attached to a wire upstream of the assembly. The nonrotating wire is for retaining the assembly in tension and enabling return of the assembly to the pipe entrance. The assembly is initially placed in the pipe or tube to be cleaned. A pressurized water or solution source is provided at a required flow-rate to propel the assembly through the pipe or tube. The upstream water pressure propels and spins the turbine, standoff support and brush. The rotating brush combined with the solution cleans the inside of the pipe. The solution flows out of the other end of the pipe with the brush rotation controlled by the flow-rate. A second embodiment is similar to the first embodiment but instead includes a circular shaped brush with ring backing mounted in the groove of the exterior ring of the turbine, and also reduces the size of the standoff support or eliminates the standoff support.

BEARING DEFECT SIGNATURE ANALYSIS USING ADVANCED NONLINEAR SIGNAL ANALYSIS IN A CONTROLLED ENVIRONMENT Final Report
T. Zoladz, E. Earhart, and T. Fiorucci Washington May 1995 48 p
(CDDF Proj. 93-10)
(NASA-TM-108491; NAS 1.15:108491) Avail: CASI HC A03/MF A01

Utilizing high-frequency data from a highly instrumented rotor assembly, seeded bearing defect signatures are characterized using both conventional linear approaches, such as power spectral density analysis, and recently developed nonlinear techniques such as bicoherence analysis. Traditional low-frequency (less than 20 kHz) analysis and high-frequency envelope analysis of both accelerometer and acoustic emission data are used to recover characteristic bearing distress information buried deeply in acquired data. The successful coupling of newly developed nonlinear signal analysis with recovered wideband envelope data from accelerometers and acoustic emission sensors is the innovative focus of this research. Advanced composites are not without trade-offs. Their increased designability brings an increase in the complexity of their internal geometry and, as a result, an increase in the number of failure modes associated with a defect. When two or more isotropic materials are combined in a composite, the isotropic material failure modes may also combine. In a laminate, matrix delamination, cracking and crazing, and voids and porosity, will often combine with fiber breakage, shattering, waviness, and separation to bring about ultimate structural failure. This combining of failure modes can result in defect boundaries of different sizes, corresponding to the failure of each structural component. This paper discusses a dual-technology NDE (Non Destructive Evaluation) (eddy current (EC) and ultrasonics (UT)) study of graphite/epoxy (gr/ep) laminate samples. Eddy current and ultrasonic raster (Cscan) imaging were used together to characterize the effects of mechanical impact damage, high temperature thermal damage and various types of inserts in gr/ep laminate samples of various stacking sequences. CAN THERE BE RELIABILITY WITHOUT RELIABILITY? Final Report
Robert J. Mislevy Oct. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-91-J-4101; RR04204)
(AD-A289480; RM-94-18-ONR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A recent article by Pamela Moss asks the title question, 'Can there be validity without reliability?' If by reliability we mean only KR-2O coefficients or inter-rater correlations, the answer is yes. Sometimes these particular indices for evaluating evidence suit the problem we encounter; sometimes they don't. If by reliability we mean credibility of evidence, where credibility is defined as 'appropriate to the intended inference, the answer is no, we cannot have validity without reliability. Because 'validity' encompasses the process of reasoning as well as the data, uncritically accepting observations as strong evidence, when they may be incorrect, misleading, unrepresentative, or fraudulent, may lead coincidentally to correct conclusions but not to valid ones. This paper discusses and illustrates a broader conception of 'reliability' in educational assessment, to ground a deeper understanding of the issues raised by Professor Moss's question. DTIC

MEASURING FAULT TOLERANCE WITH THE FTAPE FAULT INJECTION TOOL
Timothy K. Tsai and Ravishankar K. Iyer [1995] 16 p Submitted for publication
(Contract NAG1-613; DABT63-94-C-0045)
(NASA-CR-197773; NAS 1.26:197773) Avail: CASI HC A03/MF A01

This paper describes FTAPE (Fault Tolerance And Performance Evaluator), a tool that can be used to compare fault-tolerant computers. The major parts of the tool include a system-wide fault-injector, a workload generator, and a workload activity measurement tool. The workload creates high stress conditions on the machine. Using stress-based injection, the fault injector is able to utilize knowledge of the workload activity to ensure a high level of fault propagation. The errors/fault ratio, performance degradation, and number of system crashes are presented as measures of fault tolerance. Author

I(SUB DDQ) TESTING AND DEFECT CLASSES: A TUTORIAL
Jerry M. Soden and Charles F. Hawkins (New Mexico Univ., Albuquerque, NM.) 1994 10 p Presented at the Custom Integrated Circuits Conference, Santa Clara, CA, 1-4 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-005467; SAND-94-3257C; CONF-9505154-1) Avail: CASI HC A02/MF A01

I(sub DDQ) testing of CMOS IC's is a technique for production quality and reliability improvement, design validation, and failure analysis. The origin and basic concepts of I(sub DDQ) testing are reviewed. The relationship of I(sub DDQ) testing to other test methods is considered in the context of the whole IC life cycle from design, fabrication, and test through end use. A comprehensive test strategy is described that uses defect classes based on defect electrical properties rather than traditional fault models. DOE

In this Progress Report, the author describes the continuing research to explore the feasibility of implementing medical linear array imaging technology as a viable ultrasonic-based nondestructive evaluation method to inspect and characterize complex materials. Images obtained using an unmodified medical ultrasonic imaging system of a bonded aluminum plate sample with a simulated disbond region are presented. The disbond region was produced by adhering a piece of plain white paper to a piece of cellophane tape and applying the paper-tape combination to one of the aluminum plates. Because the area under the paper was not adhesively bonded to the aluminum plate, this arrangement more closely simulates a disbond. Images are also presented for an aluminum plate sample with an epoxy strip adhered to one side to help provide information for the interpretation of the images of the bonded aluminum plate sample containing the disbond region. These images are compared with corresponding conventional ultrasonic contact transducer measurements in order to provide information regarding the nature of the disbonded region. The results of this on-going investigation may provide a step toward the development of a rapid, real-time, and portable method of ultrasonic inspection and characterization based on linear array technology. In Section 2 of this Progress Report, the preparation of the aluminum plate specimens is described. Section 3 describes the method of linear array imaging. Sections 4 and 5 present the linear array images and results from contact transducer measurements, respectively. A discussion of the results are presented in Section 6. Derived from text

MANUAL FOR SHOCK3D, VERSION 2.0. COMPUTER PROGRAM FOR NON-LINEAR SHOCK RESPONSE
B. Q. Westgeest and R. Regoord 26 Aug. 1994 93 p Sponsored by Ministry of Defence Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288631; TNO/R-94-CMC-R0539; TDCK-TD-94-2019) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The program SHOCK3D deals with the shock response of a 3D structure, being composed from elastic parts, rigid bodies and non-linear mountings. Shock loading is in the form of prescribed shock motions as they are defined by several Navies in Equipment Shock Specifications (UNDEX shock) or in the form of prescribed forces. Mass- and stiffness matrices for the elastic parts are assembled within a separate f.e.m. program. A transient response analysis leads to time histories which can be plotted. Test problems have been added. A pc version may be used in case there is no need to include elastic parts. DTIC

ANALYSIS AND DEVELOPMENT OF FINITE ELEMENT METHODS FOR THE STUDY OF NONLINEAR THERMOMECHANICAL BEHAVIOR OF STRUCTURAL COMPONENTS Final Contractor Report
J. Tinsley Oden Cleveland, OH NASA May 1995 152 p
(Grant NAG3-329; RTOP 505-63-5B)
(NASA-CR-195354; E-9005; NAS 1.26:195354) Avail: CASI HC A08/MF A02

Underintegrated methods are investigated with respect to their stability and convergence properties. The focus was on identifying regions where they work and regions where techniques such as hourglass viscosity and hourglass control can be used. Results obtained show that underintegrated methods typically lead to finite element stiffness with spurious modes in the solution. However, problems exist (scalar elliptic boundary value problems) where underintegrated with hourglass control yield convergent solutions. Also, stress averaging in underintegrated stiffness calculations does not necessarily lead to stable or convergent stress states. Author

USER'S GUIDE: COMPUTER PROGRAM FOR ANALYSIS OF BEAM-COLUMN STRUCTURES WITH NONLINEAR SUPPORTS (CBEAMC) Final Report
William P. Dawkins Nov. 1994 113 p Sponsored by Army Corps. of Engineers Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289031; WES/IR/ITL-94-6; ITL-94-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report documents a computer program--CBEAMC--for analysis of general beam-column structures supported and/or loaded by components which interact with displacements of the beam and/or column. Chapter 2 describes the general beam-column system considered and the mathematical model used for analysis; Chapter 3 presents the force-displacement relationships for the mathematical model and describes the computational procedure used for solution; and Chapter 4 provides example solution obtained with the program. The computer program described in this report has been checked to ensure that the results are accurate within the limitations of the procedures employed. However, there may be unusual situations which were not anticipated, and these situations may cause the program to produce questionable results. It is the responsibility of the user to judge the validity of the results. No responsibility is assumed by the author for the design or behavior of any structure based on results obtained with the program. DTIC

ANALYSIS OF FATIGUE FRACTOGRAPHIC DATA OF A ROD END HOUSING USING A MONTE CARLO SIMULATION
Toshiyuki Shgimokawa and Yoshiaki Kakuta Feb. 1994 15 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1225) Avail: CASI HC A03/MF A01

This paper presents a new method using a Monte Carlo simulation to estimate a life distribution of fatigue crack propagation on the basis of crack length versus striation spacing data. This simulation is based on the distributions of two parameter estimates of a regression line and the reasonable correlation of the two parameter estimates. One cycle of the Monte Carlo scheme generates a set of parameter estimates which give a life of fatigue crack propagation. The analyzed data were obtained by scanning electron microscope (SEM) observation of a fatigue fracture surface of the rod end housing of a hydraulic actuator, which was used for a main landing gear in transport aircraft. A conventional regression analysis provides a set of two deterministic-parameter estimates, a life estimate of fatigue crack propagation, and the statistical properties of striation spacing. Stochastic-process modes of crack growth and practical probabilistic methods including the proposed method are used to estimate the life distributions of fatigue crack propagation on the basis of the results of the regression analysis. The obtained results are discussed and compared. The proposed method approximates the fatigue life of the rod end housing as the B-allowable life when the initial crack length is assumed to be 0 mm. EFFECT OF SURFACE COATING ON ONE-DIMENSIONAL SYSTEM SUBJECTED TO UNIT STEP PRESSURE WAVE Progress Report, 1 Oct. 1993 - 30 Sep. 1994
T. P. Brasek, Y. W. Kwon, and Y. S. Shin 30 Sep. 1994 51 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract MIPR-94-573)
(AD-A288237; NPS-ME-94-006) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The response of a one-dimensional, coated, aluminum structure subjected to a unit step pressure wave is studied. The coating is either an elastic material or a viscoelastic tread stock rubber of variable stiffness; it separates the structure from an air or a water medium. The stress and nodal velocity of the structure coated with different materials is compared to a system without a coating (homogeneous system). Both the stress and nodal velocity of the structure increase with a decreasing coating stiffness regardless of the coating type or bounding medium. This phenomenon indicates that the coating stiffness governs the degree of strain energy release from the structure to the medium. A softer coating appears to trap this excess energy increasing the stress in the structure. In all cases studied, the stiffer coating reduced the dynamic response of the structure when compared to the homogeneous system. A rubber shear modulus of approximately 6000 psi and greater ensured a favorable dynamic response for a coated aluminum structure enacted upon by a step pressure wave travelling in either air or water. The threshold value may vary depending upon the geometry and material properties of both the coating and the structure. DTIC

PROCEEDINGS: WORKSHOP ON RESEARCH NEEDS IN WIND ENGINEERING
R. D. Marshall Feb. 1995 78 p Workshop held in Gaithersburg, MD, 12-13 Sep. 1994
(PB95-189528; NISTIR-5597) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report presents findings and recommendations developed at a workshop on research needs in wind engineering. Representatives from universities, the private sector, and Federal agencies presented program overviews and participated in working group sessions addressing various aspects of wind engineering research and wind disaster mitigation. Research needs and topics for technology transfer were identified and prioritized. It was concluded that current funding of wind engineering research in the United States falls far short of what is needed to effectively address the problem of spiraling losses due to wind damage. There is, however, considerable wind engineering knowledge now available for implementation by the model building codes and by the building industry in general. NTIS

ANALYSIS OF PLATE-TWIST TEST FOR IN-PLANE SHEAR MODULUS OF COMPOSITE MATERIALS (REVISED)
G. D. Sims, W. Nimmo, A. F. Johnson, and D. H. Ferriss Jan. 1994 16 p
(PB95-190195; NPL-DMM(A)-54-Rev) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In this report an improved analysis of the plate-twist test for the measurement of in-plane shear modulus of composite materials and the shear modulus of isotropic materials is described and experimentally validated. The analysis removes errors connected with the position of the loading points and allows greater freedom in their positioning. In particular it is no longer necessary to position the loading points exactly on the corners of the plate. An error of 1.0 mm in the positioning of the loading points on a 150 mm square plate results in an error of 3.4% in the measured shear modulus. A draft standard has been produced for this test method, which will be used in a round-robin exercise to obtain precision data. The existing standards for the use of this method to measure the shear modulus of wood products will be checked, as they may have similar sources of error to those evaluated in this report. NTIS

N95-26839 Naval Postgraduate School, Monterey, CA.
STUDY OF DAMAGE EVOLUTIONS IN COMPOSITE PLATES SUBJECTED TO BENDING LOADS USING MICRO-MACRO ANALYSIS M.S. Thesis
Bruce Howard Hamilton Sep. 1994 62 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288523) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this study is to develop a computer program that will predict the damage progression in composite plates subjected to bending loads. Kwon's micromechanical model is used to compute the smeared effective moduli from the material properties of fiber and matrix as well as to determine stresses at the constituent level. Failure criteria based on micro-stresses are then applied to determine the extent and type of damage that occur in the composite under various loading conditions. The progression of damage throughout the composite until complete failure of the composite can then be simulated using the current computer program. The numerical prediction for a laminated composite plate containing a hole and subjected to a bending load agrees well with the experimental data. DTIC

THE COLLAPSE OF COMPOSITE CYLINDRICAL PANELS WITH VARIOUS THICKNESS USING FINITE ELEMENT ANALYSIS M.S. Thesis
Christopher P. Chaplin Dec. 1994 149 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289370; AFIT/GA/ENY/94D-4) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study compared numerical collapse results of graphite/epoxy cylindrical panels with free vertical edges undergoing axial compression for three different shell theories. Symmetric quasi-isotropic laminates were investigated using solid panels and panels with five different centralized cutouts with three thicknesses. The theories compared in the study were the Simplified Large displacement moderate Rotation (SLR) theory, the Donnell Cylindrical Shell (Modified Donnell) theory, and the Classical Donnell theory. The purpose of the study was to determine when large rotations and through-the-thickness shear become important in the numerical collapse analysis of cylindrical composite shells. By observing cases where the numerical collapse results for each of the three theories differed noticeably (greater than 3%), it could be determined when large rotations and through-the-thickness shear were important. The effects of large rotations were noticed in nearly all of the panels with large cutouts (greater than 3% panel area). Large rotations were also found to be important for thicker panels with either no cutout or a small cutout. The effects of through-the-thickness shear were only noticed in the thickest panels with large cutouts. DTIC

CHARACTERIZATION OF THE MEMBRANE THEORY OF A CLAMPED SHELL. THE HYPERBOLIC CASE
J. Piila Oct. 1994 29 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-185021; RR-A337) Avail: CASI HC A03

We study the membrane-dominated deformation state of a thin shell, the midsurface of which is located on a hyperbolic surface of revolution. The lateral shape of the shell is assumed to be that of a curvilinear polygon. The shell is loaded by a surface traction and rigidly supported throughout its edge. Proceeding from the classical shell model of Koiter-Sanders-Novozhilov, an asymptotic membrane-theory model is constructed to describe the limit behavior of the shell as the thickness tends to zero. Mathematical characteristics of the membrane theory are analyzed and the convergence rate estimate between the two models is proven. NTIS

INVESTIGATION INTO THE BEHAVIOR OF GEOMETRICALLY NONLINEAR COMPOSITE ARCHES M.S. Thesis
John C. Bailey Dec. 1994 110 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289258; AFIT/GAE/ENY/94D-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research modifies the existing finite element formulation of a potential energy based large deformation and moderate rotation theory. Hermitian shape functions replace the existing linear bending angle interpolations. Negligible differences between the two formulations indicate the underlying kinematics limit the accuracy, not the finite element interpolations. Using the new program, numerous nonlinear arch geometries are modeled to investigate the effects of arc length and thickness variations. Local and global snapping phenomena are captured as well as through the thickness shear driven nonlinearities. DTIC

AN EXPERIMENTAL INVESTIGATION OF SANDWICH FLAT PANELS UNDER LOW VELOCITY IMPACT M.S. Thesis

Timberlyn M. Harrington Dec. 1994 274 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289420; AFIT/GAE/ENY/94D-22) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This study evaluated the failure modes and mechanisms associated with increasing face sheet thickness of flat sandwich panels under low velocity impact. The sandwich panels were fabricated using 1.27 cm thick, 145 kg/cu m (9 lb/cu ft), 3.175 mm (1/8 in.) cell size Nomex honeycomb core, FM 300-2 film adhesive and AS4/3501-6 graphite/epoxy face sheets. The thickness of the core remained 1.27 cm, and the thickness of the adhesive remained 0.25 mm. The thickness of the face sheets varied using the following stacking sequences: (O/90)s, (O/90)2s, (O/90)4s, (O/90)8s, and (O/90)12s. The sandwich panels were subjected to various low velocity impacts using the Dynatup Impact Test Machine. Pulse-Echo C-scans and optical microscopy of panel cross-sections were performed to characterize the damage. The cross-sections indicated that delamination and transverse cracking contribute to internal damage of the face sheets, while crushing, buckling, and crippling contribute to damage of the core. Cracks in the adhesive also contribute to damage in some cases. DTIC

PROBABILISTIC SIMULATION OF LONG TERM BEHAVIOR IN POLYMER MATRIX COMPOSITES

A. R. Shah (NYMA, Inc., Brook Park, OH.), S. N. Singhal (NYMA, Inc., Brook Park, OH.), P. L. N. Murthy, and C. C. Chamis Apr. 1995 21 p Presented at the 35th Structures, Structural Dynamics and Materials Conference, Hilton Head, SC, 18-21 Apr. 1994; sponsored by AIAA, ASME, AHS, and ASCE

(Contract NAS3-27186; RTOP 505-62-10)

(NASA-TM-106893; E-9537; NAS 1.15:106893; AIAA Paper 94-1445) Avail: CASI HC A03/MF A01

A methodology to compute cumulative probability distribution functions (CDF) of fatigue life for different ratios, r of applied stress to the laminate strength based on first ply failure criteria has been developed and demonstrated. Degradation effects due to long term environmental exposure and mechanical cyclic loads are considered in the simulation process. A unified time-stress dependent multi-factor interaction equation model developed at NASA Lewis Research Center has been used to account for the degradation/aging of material properties due to cyclic loads. Fast probability integration method is used to perform probabilistic simulation of uncertainties. Sensitivity of fatigue life reliability to uncertainties in the primitive random variables are computed and their significance in the reliability based design for maximum life is discussed. The results show that the graphite/epoxy (0/+45/90) deg laminate with ply thickness 0.125 in. has 500,000 cycles life for applied stress to laminate strength ratio of 0.6 and a reliability of 0.999. Also, the fatigue life reliability has been found to be most sensitive to the ply thickness and matrix tensile strength. Tighter quality controls must therefore be enforced on ply thickness and matrix strength in order to achieve high reliability of the structure. Author

THE EFFECTS OF FINITE ELEMENT GRID DENSITY ON MODEL CORRELATION AND DAMAGE DETECTION OF A BRIDGE

Todd Simmermacher, R. L. Mayes, G. M. Reese, G. H. James, and David Zimmerman (Houston Univ., TX.) 1995 16 p Presented at the AIAA Adaptive Structures Conference, New Orleans, LA, 13-14 Apr. 1995

(Contract DE-AC04-94AL-85000)

(DE94-018895; SAND-94-2082C; CONF-950444-1) Avail: CASI HC A03/MF A01

Variation of model size as determined by grid density is studied for both model refinement and damage detection. In model refinement, it is found that a large model with a fine grid is preferable in order to achieve a reasonable correlation between the experimental response and the finite element model. A smaller model falls victim to the inaccuracies of the finite element (FE) method. As the grid become increasing finer, the FE method approaches an accurate representation. In damage detection the FE method is only a starting point. The model is refined with a matrix method which doesn't retain the FE approximation; therefore a smaller model that captures most of the dynamics of the structure can be used and is preferable. DOE

SCALING ISSUES IN DYNAMIC FRAGMENTATION

Dennis Grady 1995 13 p Presented at the Defense Nuclear Agency Workshop on Scaling Aspects of Hardened Structures, Albuquerque, NM, 24-26 Jan. 1995 Prepared in cooperation with AT and T Technologies, Inc., Albuquerque, NM

(Contracts DE-AC04-94AL-85000; DE-AC04-76DP-00789)

(DE95-008509; SAND-94-3187C; CONF-950169-1) Avail: CASI HC A03/MF A01

A set of relations which would allow the experimental results of impact fragmentation experiments conducted under the controlled environment of a testing laboratory to be confidently scaled to realistic system dimensions would be an effective tool in the developments toward a predictive capability in full scale applications involving fragmentation. Here some of the issues governing scaling relations in dynamic fragmentation are discussed. Dimensional arguments are pursued. Some of the consequences indicate that fragmentation scaling relations are dependent on the specific material properties and mechanisms governing the fragmentation process. Transitions in functional forms of the scaling relations can be expected under conditions in which fragmentation mechanism transitions occur in complex engineering materials. Some computational simulations and experimental impact fragmentation results are examined. DOE

A MICROSTRUCTURALLY BASED MODEL OF SOLDER JOINTS UNDER CONDITIONS OF THERMOMECHANICAL FATIGUE

D. R. Frear, S. N. Burchett, and M. M. Rashid (California Univ., Davis, CA.) 1994 14 p Presented at the InterPack '95: International Electronic Packaging Conference, Maui, HI, 26-30 Mar. 1995

(Contract DE-AC04-94AL-85000)

(DE95-006226; SAND-94-0951C; CONF-950344-5) Avail: CASI HC A03/MF A01

The thermomechanical fatigue failure of solder joints is increasingly becoming an important reliability issue. We present two computational methodologies that have been developed to predict the behavior of near eutectic Sn-Pb solder joints under fatigue conditions that are based on metallurgical tests as fundamental input for constitutive relations. The two-phase model mathematically predicts the heterogeneous coarsening behavior of near eutectic Sn-Pb solder. The finite element simulations from this model agree well with experimental thermomechanical fatigue tests. The simulations show that the presence of an initial heterogeneity in the solder microstructure could significantly degrade the fatigue lifetime. The single phase model is a computational technique that was developed to predict solder joint behavior using materials data for constitutive relation constants that could be determined through straightforward metallurgical experiments. A shear/torsion test sample was developed to impose strain in two different orientations. Materials constants were derived from these tests and the results showed an adequate fit to experimental results. The single-phase model could be very useful for conditions where microstructural evolution is not a dominant factor in fatigue. DOE

EXPERIMENTAL STUDIES TO TEST SIMPLE FLEXURAL NEUTRALIZERS FITTED TO BEAMS

P. Clark and R. G. White Oct. 1994 53 p Sponsored by the Marine Technology Directorate Ltd, the Science and Engineering Research Council, and the Procurement Executive, Ministry of Defence
(ISVR-TR-239) Copyright Avail: Issuing Activity (Southampton Univ., Southampton, England)

The control of vibration in one-dimensional structures is of considerable interest in practical engineering. With the majority of industrial machinery installations, it is this type of structure, for example, beams, pipework vibrating at low frequencies and other mechanical linkages, which forms one of the main vibration paths that bypass isolator systems. It is of interest to consider discontinuities that may be incorporated into these types of structure since they significantly affect the vibration characteristics of the complete installation. One such discontinuity that may be employed in vibration control is the vibration neutralizer. Previous work in this area of research has developed theoretical models of the neutralizer performance as a vibration control technique with particular reference to the effect of incorporating alternative mounting methods. In this work, complementary experimental studies are presented with a view to validating those theoretical studies previously undertaken. Author

Structural analyses are developed to determine the linear elastic and the geometrically nonlinear elastic response of an internally pressurized, orthogonally stiffened, composite material cylindrical shell. The configuration is a long circular cylindrical shell stiffened on the inside by a regular arrangement of identical stringers and identical rings. Periodicity permits the analysis of a unit cell model consisting of a portion of the shell wall centered over one stringer-ring joint. The stringer-ring-shell joint is modeled in an idealized manner; the stiffeners are mathematically permitted to pass through one another without contact, but do interact indirectly through their mutual contact with the shell at the joint. Discrete beams models of the stiffeners include a stringer with a symmetrical cross section and a ring with either a symmetrical or an asymmetrical open section. Mathematical formulations presented for the linear response include the effect of transverse shear deformations and the effect of warping of the ring's cross section due to torsion. These effects are important when the ring has an asymmetrical cross section because the loss of symmetry in the problem results in torsion and out-of-plane bending of the ring, and a concomitant rotation of the joint at the stiffener intersection about the circumferential axis. Data from a composite material crown panel typical of a large transport fuselage structure are used for two numerical examples. Although the inclusion of geometric nonlinearity reduces the 'pillowing' of the shell, it is found that bending is localized to a narrow region near the stiffener. Including warping deformation of the ring into the analysis changes the sense of the joint rotation. Transverse shear deformation models result in increased joint flexibility. Author

ROBUST INTEGRATION SCHEMES FOR GENERALIZED VISCOPLASTICITY WITH INTERNAL-STATE VARIABLES. PART 1: THEORETICAL DEVELOPMENTS AND APPLICATIONS Final Report
Atef F. Saleeb and Wei Li May 1995 79 p Original contains color illustrations
(Grant NAG3-1493; RTOP 505-63-5B)
(NASA-CR-195452-Pt-1; E-9534-Pt-1) Avail: CASI HC A05/MF A01; 5 functional color pages

This two-part report is concerned with the development of a general framework for the implicit time-stepping integrators for the flow and evolution equations in generalized viscoplastic models. The primary goal is to present a complete theoretical formulation, and to address in detail the algorithmic and numerical analysis aspects involved in its finite element implementation, as well as to critically assess the numerical performance of the developed schemes in a comprehensive set of test cases. On the theoretical side, the general framework is developed on the basis of the unconditionally-stable, backward-Euler difference scheme as a starting point. Its mathematical structure is of sufficient generality to allow a unified treatment of different classes of viscoplastic models with internal variables. In particular, two specific models of this type, which are representative of the present start-of-art in metal viscoplasticity, are considered in applications reported here; i.e., fully associative (GVIPS) and non-associative (NAV) models. The matrix forms developed for both these models are directly applicable for both initially isotropic and anisotropic materials, in general (three-dimensional) situations as well as subspace applications (i.e., plane stress/strain, axisymmetric, generalized plane stress in shells). On the computational side, issues related to efficiency and robustness are emphasized in developing the (local) interative algorithm. In particular, closed-form expressions for residual vectors and (consistent) material tangent stiffness arrays are given explicitly for both GVIPS and NAV models, with their maximum sizes 'optimized' to depend only on the number of independent stress components (but independent of the number of viscoplastic internal state parameters). Significant robustness of the local iterative solution is provided by complementing the basic Newton-Raphson scheme with a line-search strategy for convergence. In the present first part of the report, we focus on the theoretical developments, and discussions of the results of numerical-performance studies using the integration schemes for GVIPS and NAV models. DEFORMATION LIMITS ON TWO-PARAMETER FRACTURE MECHANICS IN TERMS OF HIGHER ORDER ASYMPTOTICS Final Report, Jan. 1992 - Sep. 1994
D. L. Crane and T. L. Anderson Sep. 1994 226 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N61533-92-K-0030)
(AD-A289113) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report addresses the limitations of two-parameter fracture mechanics. We performed an asymptotic analysis of the general power series representation of the crack tip stress potential in an elastic plastic material that obeys a Ramberg-Osgood constitutive law. Expansion of the power series over a substantial number of terms yields. only three independent coefficients for low. and medium-hardening materials. The first independent The second and third independent coefficients, K2 and K4 are a function of geometry and loading level. A two-parameter theory implies that the crack tip stress fields have two degrees of freedom, but the asymptotic analysis implies that three parameters are required to characterize near-tip conditions. Thus two-parameter fracture theory is a valid engineering model only when there is an approximately unique relationship between K2 and K4. We performed elastic-plastic finite element analyses on several geometries and evaluated K2 and K4 as a function of deformation level. A reference,two-parameter solution (which gives a unique relation between K2 and K4) was provided by the modified boundary layer (MBL) geometry. Results indicate that the near tip stresses in all but the deeply cracked SENT (a/W-.5.O.9) and SENT (a/W-0.9) lend themselves to a two-parameter characterization. However, the deeply cracked SENT and SENT specimens maintain a high level of constraint to relatively large deformation levels. Thus single-parameter fracture mechanics is fairly robust for these high constraint geometries, but two-parameter theory is of little value when constraint loss eventually occurs. DTIC

Cleavage fracture toughness can be influenced by specimen dimensions. Crack tip constraint can relax in small specimens, resulting in higher apparent toughness. Moreover, there is a statistical sampling effect, where thicker specimens tend to have lower toughness than thin specimens due to an increased sample volume. In deeply notched bend and compact specimens, theoretical modeling, finite element analysis, and experimental data indicate that the results will not be significantly influenced by crack tip constraint as long as the following specimen size requirements are met: a/W greater than 0.5, B greater than or equal to MJ(c)/sigma(y), B/b greater than or equal to 1 where a is the crack length, W is the specimen width, B is the specimen thickness, b is the uncracked ligament, J(c) is the critical 3 value, sigma(y) is the effective yield strength and M is a dimensionless constant. These size requirements are conservative if M is set equal to 100; M- 50 appears to be adequate for many materials, but the authors recommend the stricter requirement until fracture validation is performed. When specimens meet the above requirements, fracture toughness should not be influenced by size, provided statistical thickness effects are taken into account. DTIC

THE SOLAR ARRAY-INDUCED DISTURBANCE OF THE HUBBLE SPACE TELESCOPE POINTING SYSTEM

C. L. Foster, M. L. Tinker, G. S. Nurre, and W. A. Till Washington May 1995 34 p

(NASA-TP-3556; M-782; NAS 1.60:3556) Avail: CASI HC A03/MF A01

The investigation of the vibrational disturbances of the Hubble Space Telescope that were discovered soon after deployment in orbit is described in detail. It was found that the disturbances were particularly evident during orbital day-night crossings, and that the magnitudes of the disturbances were considerably larger than the design jitter requirements. This paper describes the process by which the vibrations were characterized and isolated to a particular mechanism. The analysis of the flight data and comparisons with computer simulation results showed that the source of the disturbances was the thermally driven deformation of the solar arrays in conjunction with frictional effects in the array mechanisms. The control system was successfully modified to attenuate the disturbances to tolerable levels pending mechanical and thermal redesign of the solar arrays. The new arrays were installed during the first space telescope servicing mission and, in combination with the enhanced control system algorithm, reduced the disturbances to satisfactory levels. COMPUTATIONAL STUDIES OF PROJECTILE MELT IN IMPACT WITH TYPICAL WHIPPLE SHIELDS

C. E. Rhoades, Jr. and M. L. Alme (Alme and Associates, Columbia, MD.) Dec. 1994 9 p Presented at the Nuclear Explosives Code Developers Conference (NECDC), Las Vegas, NV, 27 Oct. 1994

(Contract W-7405-eng-48)

(DE95-005916; UCRL-JC-118566; CONF-9410254-4) Avail: CASI HC A02/MF A01

Protecting space-based structures against the impact of orbital debris is an important problem of current interest. This paper presents scaling results based on simulations with the CALE computer program of aluminum projectile impacting typical aluminum Whipple shields at speeds of 6 to 14 km/sec. The objective was to determine the extent of projectile and shield material melting. The approach was to perform a matrix of computer simulations varying the impact speed from 6 to 14 km/sec and varying the areal density of the shield from 5 percent to 80 percent of the centerline areal density of the projectile. The projectile radius was fixed at 9.5 mm (mass = 1.27 grams). The melt state of the projectile material and the shield material was assessed after release of the initial shock. The post-release specific energy in the projectile and in the shield was compared with the enthalpy of incipient melt and the enthalpy of complete melt provided in the Hultgren Tables. Material with specific energy greater than the enthalpy of complete melt was assumed to be fully melted. Material with specific energy greater than the enthalpy of incipient melt but less than that of complete melt was assumed to be partially solid and partially melted mixed phase material with no strength. Material with specific energy less than the enthalpy of incipient melt was assumed to be in a solid state with strength. It is likely that this solid material is in a highly fragmented state as a result of the initial shock. DOE

INVESTIGATION OF HE DRIVEN CYLINDRICAL LINER

Tai-Ho Tan 1995 9 p Presented at the 4th International Symposium on Behavior and Dense Media Under High Dynamic Pressure, Tours, France, 5-9 Jun. 1995

(Contract W-7405-eng-36)

(DE95-007866; LA-UR-95-686; CONF-9506142-1) Avail: CASI HC A02/MF A01

We developed a technique that can compress most materials to densities much higher than their original values and shock them hard enough to undergo phase changes to various partially ionized states. The process involves using high explosives to drive a thin cylindrical liner so that it will progressively implode and converge along the axis at very high velocity. The device is simple yet versatile. Its configuration is ideally suited as a compact laboratory for the investigation of the behavior of dense media under extreme conditions. Code simulations show that liners made from most metals can be successfully imploded to converge on axis, producing over 10 MB pressure. For example, a 2D hydrocode calculation predicts that in a simple configuration where a hollow core PBX-9501 explosive cylinder is corner initiated to drive a thin seamless 304 SS tubing, the final convergence velocity can exceed 1 cm/(mu)s to produce a 15 MB pressure at impact as the density increases to 19.5 g/cc. The temperature from shock heating rises rapidly above 8 eV, and the result is a combination of radiation and plasma emissions. We have carried out several experiments with a wide array of diagnostics to investigate the implosion dynamics and final state interaction phenomena, and the results are compared with the code predictions. Radiographs of the liner implosion strongly indicate that the hydrodynamic processes are well behaved and calculable. Temperature measurement from the optical radiation is generally consistent with the code prediction. The velocity of the plasma front is measured by using optical pins and fast framing photography, and is found to lie between 11-17 cm/(mu)s. Fast framing photographs were taken with the aid of self luminous light to observe the evacuated chamber inside the imploding liner. The experimental results and their comparison with the calculation are discussed. DOE

INSPECTION METHODS FOR UNDERWATER CABLES M.S. Thesis
Robin Y. Noyes 14 Dec. 1994 140 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289610) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Underwater cables serve many purposes, both military and commercial. The most common use of underwater cables is for telecommunications, where voice is transformed into either electrical current or pulses of laser light which are transmitted across the world's oceans via underwater cables. The military uses underwater cables in several ways in support of national defense. Hydrophone arrays deployed from underwater cables form an extensive integrated undersea surveillance system (RYSS) which is used to monitor the activities of submannes. The military also uses underwater cables for training, testing, and evaluation ranges in the ocean. These ranges use transponder units to track air, surface, and submerged targets for purposes such as measuring surface ship radiated noise or evaluating weapons systems accuracy. The underwater cables provide the means to transmit communications and data to control facilities. DTIC

42 GEOSCIENCES (GENERAL)

N95-28099 Minnesota Univ., Minneapolis, MN. Inst. for Matematics and its applications
EMERGING APPLICATIONS OF PROBABILITY (STOCHASTIC MODELS IN GEOSYSTEMS) Final Report, 1 Jan. - 31 Jul. 1994
Avner Friedman 16 Dec. 1994 21 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-94-1-0301)
(AD-A289117) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The workshop was devoted to several of the most active topics in this area and, in particular, covered: Probabilistic models in geophysics including hierarchical models for geophysical structures, homogenization of random elastic media, propagation of seismic waves, statistical methods for estimation of parameters of seismic waves, prediction problems for seismic phenomena and other geophysical fields. Modern probabilistic and statistical methods in oceanography and atmospheric sciences including: probabilistic and statistical mechanical models of large scale ocean circulation; random fields and stochastic partial differential equations techniques; waves in the ocean in presence of random topography and random forcing, random field modeling of salinity, temperature and other physical fields; weak turbulence; prediction problems; distribution functions for vorticity, velocity and dissipation rates; intermittency and structure functions; singularities in Euler equations and their relation to turbulence; and turbulent cascades and martingales. DIGITAL MAPPING, CHARTING, AND GEODESY ANALYSIS PROGRAM: INITIAL TECHNICAL REVIEW OF RASTER PRODUCT FORMAT Final Report
Kevin B. Shaw, John Breckenridge, S. D. Coughlan, Tom Fetterer, Ruth Guldry, Jerry Landrum, Greg Terrie, Susan V. Carter, Steve Kuder, and H. Vincent Miller (Mississippi State Univ., Bay Saint Louis, MS.) 31 Oct. 1994 18 p Sponsored by Oceanographer of the Navy Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289039; NRL/MR/7441-94-7546) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Rounding out the Defense Mapping Agency's (DMA) effort for a raster standard to complement the existing Vector Product Format and proposed Text Product Standard, the Raster Product Format (RPF), is the proposed format for accommodating raster data. The Naval Research Laboratory's Digital Mapping, Charting, and Analysis Program (DMAP) has been requested by DMA (via NO96) to establish the usefulness of such a standard for naval purposes. In its technical review, DMAP discusses the overall view of a raster standard and how the development of such a standard should proceed. The RPF, for example, should be modified to be compatible with already-existing standards. The suitability of RPF as it currently exists is also discussed by DMAP. DTIC

RADIOMETER MEASUREMENTS OF SNOW IN SODANKYLAE, 1991-1993
Lauri Kurvonen Sep. 1994 104 p
(ISSN 0786-8154)
(PB95-184966; Rept-16; ISBN-951-22-2274-4) Avail: CASI HC A06/MF A02

A helicopter-borne multifrequency radiometer (24, 34, 48 and 94 GHz vertical polarization) was used to investigate the behavior of the brightness temperature of snow in Sodankyla. Several measurements were made in dry, wet and no snow conditions. The angle of incidence was 45 deg in all measurements. The radiometer measurements and their analyses are presented. The analyses have focused on the effect of vegetation and land type on the brightness temperature of snow. The aim of the study is to determine: (1) the general behavior of the brightness temperature of snow in different land types; (2) the effect of forest vegetation on the brightness temperature of snow; (3) the capability of the radiometer system to discriminate refrozen snow patches in forests during the melting period; and (4) the brightness temperature of dry snow versus the water equivalent of snow. DIGITAL MAPPING, CHARTING, AND GEODESY ANALYSIS PROGRAM TECHNICAL REVIEW OF VECTOR QUANTIZATION (VQ) DECOMPRESSION FOR THE NATIONAL IMAGERY TRANSMISSION FORMAT STANDARD (NITFS) Final Report

H. Vincent Miller (Mississippi State Univ., Bay Saint Louis, MS.), S. Danette Coughlan, Thomas A. Fetterer, Ruth A. Guidry, Maura C. Lohrenz, Mike E. Trenchard, Perry B. Wischow, Kevin B. Shaw, and Susan V. Carter 30 Nov. 1994 16 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288998; NRL-MR/7441-94-7541) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Draft Military Standard Vector Quantization (VQ) Decompression for the National Imagery Transmission Format Standard, providing a format for images compressed via a VQ scheme, has been reviewed by the Naval Research Laboratory's Digital Mapping, Charting, and Geodesy Analysis Program (DMAP) at the request of the Oceanographer of the Navy. The written standard itself is practically complete; DMAP provides exact details on essential modifications to the document. In addition, suggested modifications and editorial comments are supplied in an effort to enhance the document. DMAP's main issue, however, is the lack of information on the relationship of this standard to the already-under-development Raster Product Format (RPF), which also provides for the compressed images and is not confined to a single compression scheme. DMAP contends that once the VQ file structure is demonstrated not to conflict with the RPF, the VQ standard will provide an acceptable format, compatible with the more comprehensive RPF, for VQ compressed images. NAVAL AVIATION SYSTEM TEAM MAPPING, CHARTING, AND GEODESY HANDBOOK Final Report

John H. Harden, Jr. and Zdenka S. Willis 15 Jul. 1994 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288590) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This handbook is specifically tailored for Naval Aviation Systems Team (TEAM) weapon systems developers. It is a primary reference for information about Mapping, Charting, and Geodesy (MC&G) support from the Defense Mapping Agency (DMA). Handbook objectives are: (1) to clarify MC&G relevance to TEAM systems development and the developer's job; (2) to guide developers in acquiring a necessary basic competence in MC&G; (3) to explain the process for getting DMA MC&G data and services; and (4) to point developers towards helping on MC&G issues within the TEAM, DMA, and elsewhere. The Handbook has the following features: (1) it is organized for browsing; (2) the Executive Gouge summarizes everything on one page; (3) details to access topical sources are located in the Where To Find It box at the end of each section; and (4) useful appendices include product statistics and list key individuals. After initial hard copy distribution, this handbook will be maintained in soft copy on the Naval Air Systems Command (NAVAIR) Head quarters Network (NHN). DTIC

AIRBORNE GEOPHYSICS AND PRECISE POSITIONING: SCIENTIFIC ISSUES AND FUTURE DIRECTIONS

1995 119 p
(LC-94-68678; ISBN-0-309-05183-5) Copyright Avail: Issuing Activity (NAS-NRC)

Since the Challenger circumnavigated the globe on its oceanographic survey in the mid-1870's, scientists have mounted extensive interdisciplinary expeditions to study large regions of the Earth. The ability to probe the Earth from remote platforms has resulted in numerous scientific advances, such as the revolutionary images of previously uncharted ocean floor that were produced by marine geophysical technology in the 1960s. These images eventually helped to trigger a major paradigm shift in the earth sciences with the development of a fundamental theory of modern geophysics, plate tectonics. The purpose of this report is to highlight the advances, both potential and realized, that airborne geophysics and precise positioning have made or can make possible to the solid earth sciences. The report first discusses the state of the art in airborne geophysics as integrated with new precise positioning systems, focusing first on the new technology to map topography and the gravity field and then on recent advances in precise positioning. The scientific goals of a focused effort in airborne geophysics, including advances in our understanding of solid earth science, global climate change, the environment, and resources are outlined. The technological advances in measurement, positioning, and aircraft design that will be required to aggressively pursue the scientific goals discussed previously are identified. The recommendations of the Committee on Geodesy for achieving the goals and directions outlined in the report are presented. Derived from text

REMOTE SENSING OF HYDROLOGIC VARIABLES IN BOREAL AREAS, PHASE 2 Final Report, Apr. 1994 - Apr. 1995

Eugene L. Peck and Thomas R. Carroll (National Weather Service, Chanhassen, MN.) May 1995 28 p
(Contract NAS5-32336)
(NASA-CR-198717; NAS 1.26:198717) Avail: CASI HC A03/MF A01

During Phase 2 airborne Gamma Radiation measurements were conducted over 48 BOREAS (boreal ecosystem atmosphere study) flight lines. Ground measurements of the soil moisture (SM) of the mineral soil and the depth and water content (WC) of the moss/humus layer were collected for calibration of the flight lines. Special attention has been given to the flight lines over, and near, the primary tower sites in the southern study area (SSA); Old Black Spruce (OBS), Old Jack Pine, Old Aspen, and Young Aspen. Multiple ground surveys (September 1993, July, August, and September 1994) show the variation of the water content of the moss/humus layers and changes in the amount of standing water near the SSA OBS tower during the period September 1993 to September 1994. All ground data, airborne estimates and locations of flight lines and ground sampling points have been submitted to BORIS (BOREAS Information System). On 8-10 September 1994 exceptionally high values of cosmic radiation were observed by the airborne gamma radiation system over the SSA. Follow up investigation has not determined the source of, or what caused, the high cosmic count rates. Author

REMOTE MEASUREMENT OF GROUND TEMPERATURE AND EMISSIVITY

J. R. Henderson Jun. 1994 12 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract W-7405-eng-48)
(DE95-008055; UCRL-JC-117673; CONF-940723-35) Avail: CASI HC A03/MF A01

TAISIR, Temperature and Imaging System InfraRed, is a nominally satellite based platform for remote sensing of the earth. One of its design features is to acquire atmospheric data simultaneous with ground data, resulting in minimal dependence on external atmospheric models for data correction. Extensive modeling of the rms error of determining a ground temperature and emissivity for a gray body has been performed as a function of integration time, spectroscopic resolution of the system, ground emissivity, atmospheric variables, and atmospheric data accuracy. We find that increased resolution improves measurement accuracy by emphasizing those regions where the atmospheric transmission is highest and atmospheric emission/absorption lowest. We find rms temperature errors (le)1K and rms emissivity errors less than 0.01 are obtainable for reasonable seeing and with sufficient information about the atmosphere. A new method is developed for modeling the dependence of the band-averaged transmission and emission. Monte Carlo simulations of satellite data taken using a multi-angle technique are used to derive signal-to-noise requirements. The applicability of those results to the TAISIR system requirements are discussed. DOE

SPECKLE SPECTRUM OF THE ERS-1 WAVEMODE PRODUCT
Jul. 1994 43 p
(PB95-196564; STF10-A94008) Avail: Issuing Activity (National Technical Information Service (NTIS))

The present report contains a brief discussion of the speckle spectrum of the ERS-1 (UWA) Wavemode product. The speckle spectrum has been determined by a simple fit to directly computed spectra from a set of imagettes. The spectrum turns out to be Gaussian in azimuth direction, whereas the functional form in the range direction is significantly different with a rather flat region up to .05/m. It is also demonstrated that the origin of the low wavenumber noise in many of the UWA spectra may simply be a lack of spectral smoothing before the spectrum is encoded into the UWA format. NTIS

METHOD FOR DETERMINING SURFACE COVERAGE BY MATERIALS EXHIBITING DIFFERENT FLUORESCENT PROPERTIES Patent
Emmett W. Chappelle, inventor (to NASA), Craig S. T. Daughtry, inventor (to NASA), and James E. McMurtrey, III, inventor (to NASA) 2 May 1995 9 p Filed 22 Nov. 1993
(NASA-Case-GSC-13539-1; US-Patent-5,412,219; US-Patent-Appl-SN-155605; US-Patent-Class-250-461.1; US-Patent-Class-250-253; Int-Patent-Class-G01N-21/64) Avail: US Patent and Trademark Office

An improved method for detecting, measuring, and distinguishing crop residue, live vegetation, and mineral soil is presented. By measuring fluorescence in multiple bands, live and dead vegetation are distinguished. The surface of the ground is illuminated with ultraviolet radiation, inducing fluorescence in certain molecules. The emitted fluorescent emission induced by the ultraviolet radiation is measured by means of a fluorescence detector, consisting of a photodetector or video camera and filters. The spectral content of the emitted fluorescent emission is characterized at each point sampled, and the proportion of the sampled area covered by residue or vegetation is calculated.

REMOTE SENSING OF THE ATMOSPHERE BY RESONANCE RAMAN LIDAR
A. J. Sedlacek, D. Harder, K. P. Leung, P. B. Zuhoski, Jr., D. Burr, and C. L. Chen Dec. 1994 4 p Presented at the 6th Optical Society of America (OSA) Meeting on Remote Sensing of the Atmosphere, Salt Lake City, UT, 6-9 Feb. 1995
(Contract DE-AC02-76CH-00016)
(DE95-007312; BNL-61283; CONF-950277-1) Avail: CASI HC A01/MF A01

When in resonance, Raman scattering exhibits strong enhancement ranging from four to six orders of magnitude. This physical phenomenon has been applied to remote sensing of the Earth's atmosphere. With a 16 inch Cassegrain telescope and spectrometer/ CCD-detector system, 70-150 ppm-m of SO2 in the atmosphere has been detected at a distance of 0.5 kilometer. This system can be used to detect/monitor chemical effluence in the atmosphere by their unique Raman fingerprints. Experimental result together with detailed resonance Raman and atmospheric laser propagation effects will be discussed. DOE

MODELS USED TO FORECAST AGRICULTURAL CORN CROPS IN THE MICRO-REGION OF RIBEIRAO PRETO-SP [MODELOS DE PREVISAO DE SAFRA AGRICOLA PARA A CULTURA DE MILHO NA MICRORREGIAO DE RIBEIRAO PRETO-SP]
Sherry ChouChen Jun. 1993 18 p In PORTUGUESE
(INPE-5513-NTC/309) Avail: CASI HC A03/MF A01

To forecast production of a specific crop, its area and yield have to be estimated in advance. In this study a comparison was made using three different approaches to estimate corn yield of the micro-region Ribeirao Preto in Sao Paulo State. The first two approaches were based on yield-weather modelling using monthly meteorological data while the third used a growth simulation model (CERES-MAIZE). Results show that the first yield-weather model is better due to its simplicity of modelling in addition to the low yield estimation errors of the independent test data set. Author

RADON TRANSFORM AND ITS APPLICATIONS IN GRIDDING AIRBORNE GEOPHYSICAL SURVEY DATA Research Report
Z. Chen and M. Peltoniemi 1995 46 p See also PB93-197283
(PB95-195533; TKK-IGE-A16) Avail: CASI HC A03/MF A01

The Radon transform method has been studied as a means of presentation of geophysical data, and in an attempt to develop a better gridding technique for line-based airborne geophysical data. The observed line-based data are usually spatially aliased because the line spacing is too large compared with the wavelength of features in the cross-track direction. Another problem for conventional gridding methods is that they tend to destroy the continuity of elongated anomalies whose strike direction is not perpendicular to the grid-line direction. The radon transform gridding method transforms the observed parallel profiles into the strike-wavenumber domain. The Fourier spectrum of the desired grid is constructed from the strike-wavenumber domain using projection-slice theorem, and the final square grid is obtained by performing an inverse Fourier transform of the spectrum. Hence, two interpolations must be made in the application of the method to line-survey geophysical data: the first one is during transforming the observed parallel profiles into the strike-wavenumber domain, and the second one during the inverse process. MODELING AND RETRIEVAL OF SNOW AND SEA ICE CHARACTERISTICS IN THE FREQUENCY RANGE 6 TO 90 GHz Final Report
J. Grandell and M. Hallikainen Mar. 1994 65 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-195467; ISBN-951-22-2364-3) Avail: Issuing Activity (National Technical Information Service (NTIS))

The aim of the study is to provide tools for the analysis of multi-frequency multi-polarization spaceborne radiometer data in the retrieval of snow and sea ice characteristics. The emphasis is laid on studying the possible advantages of using higher frequency channels (up to 90 GHz). The most advanced spaceborne radiometers currently in operation (Special Sensor Microwave Imager SSM/I) or under consideration (Multi-Frequency Imaging Microwave Radiometer MIMR), operate in a frequency range up to 90 GHz. Chapter headings include: Data Acquisition; Retrieval of Snow Parameters from SSM/I Data; Retrieval of Sea Ice Parameters from SSM/I Data; Verification of Emission Algorithms Using SSM/I Data; Measurements With The HUT (Helsinki University of Technology) Radiometer System; Measurements With The HUTSCAT Scatterometer; Software Developed During the Study. FEASIBILITY OF FLYWHEEL ENERGY STORAGE SYSTEMS FOR APPLICATIONS IN FUTURE SPACE MISSIONS Final Contractor Report
G. Espiritu Santo, S. P. Gill, J. F. Kotas, and R. Paschall Jan. 1995 152 p
(Contract NAS3-25808; RTOP 476-14-10)
(NASA-CR-195422; E-9367; NAS 1.26:195422) Avail: CASI HC A08/MF A02

The objective of this study was to examine the overall feasibility of deploying electromechanical flywheel systems in space used for excess energy storage. Results of previous Rocketdyne studies have shown that the flywheel concept has a number of advantages over the NiH2 battery, including higher specific energy, longer life and high roundtrip efficiency. Based on this prior work, this current study was broken into four subtasks. The first subtask investigated the feasibility of replacing the NiH2 battery orbital replacement unit (ORU) on the international space station (ISSA) with a flywheel ORU. In addition, a conceptual design of a generic flywheel demonstrator experiment implemented on the ISSA was completed. An assessment of the life cycle cost benefits of replacing the station battery energy storage ORU's with flywheel ORU's was performed. A fourth task generated a top-level development plan for critical flywheel technologies, the flywheel demonstrator experiments and its evolution into the production unit flywheel replacement ORU. A major program of research and development projects on wind turbines for generating electricity was conducted at the NASA Lewis Research Center from 1973 to 1988. Most of these projects were sponsored by the U.S. Department of Energy (DOE), as a major element of its Federal Wind Energy Program. One other large-scale wind turbine project was sponsored by the Bureau of Reclamation of the Department of Interior (DOI). The peak years for wind energy work at Lewis were 1979-80, when almost 100 engineers, technicians, and administrative personnel were involved. From 1988 their conclusion in 1995, NASA wind energy activities have been directed toward the transfer of technology to commercial and academic organizations. Wind energy activities at NASA can be divided into two broad categories which are closely related and often overlapping: (1) Designing, building, and testing a series of 12 large-scale, experimental, horizontal-axis wind turbines (HAWT's); and (2) conducting supporting research and technology (SR&T) projects. The purpose of this bibliography is to assist those active in the field of wind energy in locating the technical information they need on wind power planning, wind loads, turbine design and analysis, fabrication and installation, laboratory and field testing, and operations and maintenance. This bibliography contains approximately 620 citations of publications by over 520 authors and co-authors. Sources are: (1) NASA reports authored by government grantee, and contractor personnel, (2) papers presented by attendees at NASA-sponsored workshops and conferences, (3) papers presented by NASA personnel at outside workshops and conferences, and (4) outside publications related to research performed at NASA/ DOE wind turbine sites. ANNEALING OF RADIATION DAMAGED GALLIUM ARSENIDE SOLAR CELLS BY LASER ILLUMINATION M.S. Thesis
Richard D. Kramer Sep. 1994 91 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289683) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In this research, preliminary results of a new approach for annealing previously irradiated Gallium Arsenide solar cells is reported. This technique examines the use of laser illumination to induce Forward-Biased current annealing. Five GaAs solar cells were irradiated with 65 MeV electrons at varying fluence levels. Visible laser light produced a 0.5 A/sq cm forward-biased current density and raised the solar cell temperature by 30 C. Ten to fifteen percent recovery of degraded parameters was achieved in four of the five tested cells. The results show that a laser can produce some annealing in radiation damaged GaAs solar cells. Further investigation into the results also indicate that the 65 MeV energy level of the electron irradiation could have caused unrecoverable permanent damage to the solar cells. Follow up research of this annealing technique should be conducted on GaAs cells that are being irradiated at a lower energy level as well as lower fluence level. Repetitive annealing of lightly damaged cells in previous research has provided appreciative recovery using forward bias current techniques. One can expect similar results using the laser induced annealing technique proposed in this research. DTIC

THE 1994 27TH ANNUAL NASA AEROSPACE BATTERY WORKSHOP
Jeffrey C. Brewer, comp. Washington Feb. 1995 638 p Workshop held in Huntsville, AL, 15-17 Nov. 1994
(NASA-CP-3292; M-772; NAS 1.55:3292) Avail: CASI HC A99/MF A06

The proceedings of the 27th Annual NASA Aerospace Battery Workshop, hosted by the Marshall Space Flight Center on November 15-17, 1994 are presented. The workshop was attended by representatives from various government agencies, as well as contractors and manufacturers, both U.S. and abroad. The subjects covered included: (1) nickel-cadium; (2) nickel-hydrogen, (3) nickel-metal hydride, and (4) lithium based technologies, as well as flight and ground test data. For individual titles, see N95-26786 through N95-26796.

The long-term performance of rechargeable battery cells has traditionally been verified through life-testing, a procedure that generally requires significant commitments of funding and test resources. In the situation of nickel hydrogen battery cells, which have the capability of providing extremely long cycle life, the time and cost required to conduct even accelerated testing has become a serious impediment to transitioning technology improvements into spacecraft applications. The utilization of computer simulations to indicate the changes in performance to be expected in response to design or operating changes in nickel hydrogen cells is therefore a particularly attractive tool in advanced battery development, as well as for verifying performance in different applications. Computer-based simulations of the long-term performance of rechargeable battery cells have typically had very limited success in the past. There are a number of reasons for the lack in progress in this area. First, and probably most important, all battery cells are relatively complex electrochemical systems, in which performance is dictated by a large number of interacting physical and chemical processes. While the complexity alone is a significant part of the problem, in many instances the fundamental chemical and physical processes underlying long-term degradation and its effects on performance have not even been understood. Second, while specific chemical and physical changes within cell components have been associated with degradation, there has been no generalized simulation architecture that enables the chemical and physical structure (and changes therein) to be translated into cell performance. For the nickel hydrogen battery cell, our knowledge of the underlying reactions that control the performance of this cell has progressed to where it clearly is possible to model them. The recent development of a relative generalized cell modelling approach provides the framework for translating the chemical and physical structure of the components inside a cell into its performance characteristics over its entire cycle life. This report describes our approach to this task in terms of defining those processes deemed critical in controlling performance over life, and the model architecture required to translate the fundamental cell processes into performance profiles. A standard Nickel-Hydrogen (NiH2) Individual Pressure Vessel (IPV) battery cell is needed to meet future low cost, high performance mission requirements for NASA, military, and civil space programs. A common or standard cell design has evolved from the heritage of HST, Milstar, and other Air Force Mantech cell designs with substantial flight experience, while incorporating some of the historical COMSAT cell design features described in a previous NASA publication. Key features include slurry process nickel electrodes having high strength, long life and high yield (lower cost), and dual layer zircar separators for improved KOH retention, uniformality, and longer life. The cell design will have a zirconium oxide wall wick inside the pressure vessel to redistribute electrolyte and extend life. The slurry electrode will be 35 mils thick to take advantage of qualified cell mechanical configurations and proven assembly and activation techniques developed by Eagle Picher Industries (EPI) for the Hubble Space Telescope (HST) RNH-90-3 and 'Generic HST' RNH-90-5 cell designs with back-to-back nickel electrodes produced by the dry sinter process. The 80Ah common cell design can be scaled to meet capacity requirements from 60Ah to 100Ah. Producibility, commonality, and long life performance will be enhanced with the robust cell design described herein. Derived from text

HIGH-RATE/HIGH-TEMPERATURE CAPABILITY OF A SINGLE-LAYER ZICAR-SEPARATOR NICKEL-HYDROGEN CELL c33
James R. Wheeler *In* NASA. Marshall Space Flight Center, The 1994 27th Annual NASA Aerospace Battery Workshop Feb. 1995 p 243-246 (For primary document see N95-26785 09-44)
Avail: CASI HC A01/MF A06

A 50 Ampere-hour nickel-hydrogen cell with a single-layer Zircar separator stack design was fully charged and then discharged at a 2C current rate to an end voltage of 1 volt. This extreme test resulted in high temperatures which were recorded at three locations on the cell, i.e., the cell wall, the boss (barrel of the compression seal), and a terminal. The results provide new information about the high-temperature and high-discharge-rate capabilities of nickel-hydrogen cells. This information also adds to the growing data base for single-layer zirconium-oxide-cloth (Zircar) separator cell designs. Author

Nickel-Hydrogen cells are being cycled under a LEO (low earth orbit) test regime to examine the benefits of operating the cells at lower States of Charge (SOC) than typically used. A group of four cells are cycled using a voltage limiting charge regime that limits the State of Charge that the cells are allowed to reach. The test cells are then compared to identical cells being cycled at or near 100% State of Charge using a constant current charge regime. Derived from text

Avail: CASI HC A03/MF A06

The George C. Marshall Space Flight Center is working to characterize aerospace AB5 Nickel Metal Hydride (NiMH) cells. The cells are being evaluated in terms of storage, low earth orbit (LEO) cycling, and response to parametric testing (high rate charge and discharge, charge retention, pulse current ability, etc.). Cells manufactured by Eagle Picher are the

subjects of the evaluation. There is speculation that NiMH cells may become direct replacements for current Nickel Cadmium cells in the near future.

Avail: CASI HC A03/MF A06

In 1992, the Naval Research Laboratory (NRL) started a program to qualify a large diameter common pressure vessel (CPV) nickel-hydrogen (NiH2) batteries for use on future Navy/NRL spacecraft electrical power subsystems. NRL's involvement with the qualification of CPV NiH2 batteries dates back to 1988 when COMSAT and Johnson Controls, Inc. initiated a joint effort to fly the first ever NiH2 CPV in space. A later NRL-JCI cooperative research and development agreement led to the launch of a space experiment in 1993 and to the use of a single NiH2 CPV battery on the BMDO Clementine spacecraft in 1994. NRL initiated procurement of two, 50 Ah CPV NiH2 batteries in the Fall of 1992. The two batteries were delivered to NRL in June 1994. NiH2 CPV batteries have almost 2x the specific energy (Wh/kg) of nickel cadium batteries and 2x the energy density (Wh/l) of individual pressure vessel NiH2 CPV's. This presentation discusses the results of electrical and mechanical qualification tests conducted at NRL. The tests included electrical characterization, standard capacity, random vibration, peak load, and thermal vacuum. The last slides of the presentation show initial results from the life cycle tests of the second NiH2 CPV battery at 40% depth of discharge and a temperature of 10 C. Derived from text

Two-cell nickel-hydrogen common pressure vessel (CPV) units with some unusual design features have been successfully built and tested. The features of interest are half-normal platinum loading for the negative electrodes, the use of rabbit-ear terminals for a CPV unit, and the incorporation of a wall wick. The units have a nominal capacity of 20 Ah and are 3.5 inches in diameter. Electric performance data are provided. The data support the growing viability of the two-cell CPV design concept. Author

The Marshall Space Flight Center (MSFC) began testing the HST Ni-H2 Six Battery Test and the 'Flight Spare Battery' Tests approximately one year before the launch of the HST. These tests are operated and reported on by the MSFC, but are managed and funded by Goddard Space Flight Center in direct support of the HST program. The HST Ni-H2 batteries are built from Eagle Picher RNH-90-3 cells. The HST EPS (electrical power system) is a direct energy transfer power system. The HST Ni-H2 Six Battery Test is a breadboard of the HST EPS. The batteries in the test are composed of test module cells and packaged into three battery modules identical to the flight modules. This test is the HST EPS testbed. The 'Flight Spare Battery' Test is a simulation of one of the six battery channels on the HST. The cells in the test are from the flight spare lot of cells, which are the same lot of cells that three of the six HST flight batteries are made from. This test is the battery life test for the HST program.

Battery management during prelaunch activities has always required special attention and careful planning. The transition from nickel-cadium to nickel-hydrogen batteries, with their high self discharge rate and lower charge efficiency, as well as longer prelaunch scenarios, has made this aspect of spacecraft battery management even more challenging. The AXAF-I Program requires high battery state of charge at launch. The use of active cooling, to ensure efficient charging, was considered and proved to be difficult and expensive. Alternative approaches were evaluated. Optimized charging, in the absence of cooling, appeared promising and was investigated. Initial testing was conducted to demonstrate the feasibility of the 'Adiabatic Charging' approach. Feasibility was demonstrated and additional testing performed to provide a quantitative, parametric data base. The assumption that the battery is in an adiabatic environment during prelaunch charging is a conservative approximation because the battery will transfer some heat to its surroundings by convective air cooling. The amount is small compared to the heat dissipated during battery overcharge. Because the battery has a large thermal mass, substantial overcharge can occur before the cells get too hot to charge efficiently. The testing presented here simulates a true adiabatic environment. Accordingly the data base may be slightly conservative. The adiabatic charge methodology used in this investigation begins with stabilizing the cell at a given starting temperature. The cell is then fully insulated on all sides. Battery temperature is carefully monitored and the charge terminated when the cell temperature reaches 85 F. Charging has been evaluated with starting temperatures from 55 to 75 F. Derived from text

The Explorer Platform/Extreme Ultraviolet Explorer (EP/EUVE) spacecraft power is provided by the Modular Power Subsystems (MPS) which contains three 50 ampere-hour Nickel Cadmium (NiCd) batteries. The batteries were fabricated by McDonnell Douglas Electronics Systems Company, with the cells fabricated by Gates Aerospace Batteries (GAB), Gainesville, Florida. Shortly following launch, the battery performance characteristics showed similar signatures as the anomalous performance observed on both the Upper Atmosphere Research Satellite (UARS) and the Compton Gamma Ray Observatory (CGRO). This prompted the development and implementation of alternate charging profiles to optimize the spacecraft battery performance. The Flight Operations Team (FOT), under the direction of Goddard Space Flight Center's (GSFC) EP/EUVE Project and Space Power Applications Branch have monitored and managed battery performance through control of the battery Charge to Discharge (C/D) ratio and implementation of a Solar Array (SA) offset. This paper provides a brief overview of the EP/EUVE mission, the MPS, the FOT's battery management for achieving the alternate charging profile, and the observed spacecraft battery performance. DEVELOPMENT OF WELDED SOLAR ARRAYS FOR DMSP AND GPS SATELLITES Technical Report
P. C. Brennan 15 Sep. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04701-93-C-0094)
(AD-A289512; TR-94(4478)-3; SMC-TR-94-48) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The integrity of welds used to join solar cells to interconnect materials was investigated in two development programs, one for DMSP and the second for GPS. Previous solar arrays for these programs utilized soldering to join the interconnect to the cells. It is critical to both programs to demonstrate the ability of the welded interconnects to withstand the thermal cycling expected on orbit. Initial test boards for DMSP indicated that additional development was necessary to generate a weld process capable of meeting mission requirements. The Aerospace Corporation was successful in improving the weld survival rates for DMSP, but ultimately recommended that the process be abandoned in favor of an alternate weld design or solder approach. The GPS design was much more successful. Weld evaluations before and after thermal cycling indicated that the GPS design was capable of surpassing mission requirements. An SEM evaluation technique, mechanical fatigue tester, and a rapid thermal-cycle tester were designed in support of these programs. This report relates the findings generated during the two development programs and discusses the reasons behind the failure of the DMSP weld program and the success of the GPS program. DTIC

ANALYSIS OF INSTABILITY GROWTH AND COLLISIONLESS RELAXATION IN THERMIONIC CONVERTERS USING 1-D PIC SIMULATIONS M.S. Thesis

Bret B. Kreh Dec. 1994 70 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289310; AFIT/GAP/ENP/94D-06) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This work investigates the role that the beam-plasma instability may play in a thermionic converter. The traditional assumption of collisionally dominated relaxation is questioned, and the beam-plasma instability is proposed as a possible dominant relaxation mechanism. Theory is developed to describe the beam-plasma instability in the cold-plasma approximation, and the theory is tested with two common Particle-in-Cell (PIC) simulation codes. The theory is first confirmed using an unbounded plasma PIC simulation employing periodic boundary conditions, ES1. The theoretically predicted growth rates are on the order of the plasma frequencies, and ESI simulations verity these predictions within the order of 1%. For typical conditions encountered in thermionic converters, the resulting growth period is on the order of 7x10(exp -11) seconds. The bounded plasma simulation PDP was used to evaluate the influence of finite geometry and the electrode boundaries. For this bounded plasma, a two-stream interaction was supported and resulted in nearly complete thermalization in approximately 5x10(exp -10) seconds. Since the electron-electron collision rate of 109 Hz and the electron atom collision rate of 107 Hz are significantly slower than the rate of development of these instabilities, the instabilities appear to be an important relaxation mechanism. SOLAR CONCENTRATOR TECHNOLOGY DEVELOPMENT FOR SPACE BASED APPLICATIONS, VOLUME 1 Final Report

A. Pintz, C. H. Castle, and R. R. Reimer 31 Dec. 1992 168 p
(Contract NCC3-77)
(NASA-CR-197723; NAS 1.26:197723; CSU-ER-1001) Avail: CASI HC A08/MF A02

Thermoelectric conversion using a radio-isotope heat source has been used where outer planetary space craft are too far away for absorbing significant solar energy. Solar dynamic power (SDP) conversion is one technology that offers advantages for applications within the inner planet region. Since SDP conversion efficiency can be 2 to 3 times higher than photovoltaic, the collecting surfaces are much reduced in area and therefore lighter. This becomes an advantage in allocating more weight to launched payloads. A second advantage results for low earth orbit applications. The reduced area results in lower drag forces on the spacecraft and requires less reboost propellant to maintain orbit. A third advantage occurs because of the sun-to-shade cycling while in earth orbit. Photovoltaic systems require batteries to store energy for use when in the shade, and battery life for periods of 10 to 15 years is not presently achievable. For these reasons the Solar Dynamics and Thermal Systems Branch at NASA LeRC has funded work in developing SDP systems. The generic SDP system uses a large parabolic solar concentrator to focus solar energy onto a power conversion device. The concentrators are large areas and must therefore be efficient and have low specific weights. Yet these surfaces must be precise and capable of being stowed in a launch vehicle and then deployed and sometimes unfurled in space. There are significant technical challenges in engineering such structures, and considerable investigation has been made to date. This is the first of two volumes reporting on the research done by the Advanced Manufacturing Center at Cleveland State University to assist NASA LeRC in evaluating this technology. The objective of the grant was to restore the solar concentrator development technology of the 1960s while improving it with advances that have occurred since then. This report summarizes the work done from January 1989 through December 1991. Derived from text

GEOTHERMAL DIRECT-HEAT UTILIZATION ASSISTANCE Quarterly Progress Report, Oct. - Dec. 1994

1994 19 p
(Contract DE-FG07-90ID-13040)
(DE95-007247; DOE/ID-13040/T26) Avail: CASI HC A03/MF A01

The report summarizes activities of the Geo-Heat Center (GHC) at Oregon Institute of Technology for the first quarter of Fiscal Year 1995. It describes contacts with parties during this period related to assistance with geothermal direct heat projects. Areas dealt with include geothermal heat pumps, space heating, greenhouses, aquaculture, resources and equipment. Research is also being conducted on geothermal energy cost evaluation, low-temperature geothermal resource assessment, use of silica waste from the Cerro Prieto geothermal field as construction materials and geothermal heat pumps. Outreach activities include the publication of a quarterly bulletin on direct heat applications and dissemination of information on low-temperature geothermal resources and utilization. DOE

A COMPARISON OF MEASURED WIND PARK LOAD HISTORIES WITH THE WISPER AND WISPERX LOAD SPECTRA

N. D. Kelley Jan. 1995 8 p Presented at the 1995 American Society of Mechanical Engineers (ASME) Energy Sources Technology Conference and Exhibition, Houston, TX, 29 Jan. - 1 Feb. 1995

(Contract DE-AC36-83CH-10093)
(DE95-000295; NREL/TP-442-7226; CONF-950116-6) Avail: CASI HC A02/MF A01

The blade-loading histories from two adjacent Micon 65/13 wind turbines are compared with the variable-amplitude test-loading histories known as the WISPER and WISPERX spectra. These standardized loading sequences were developed from blade flapwise load histories taken from nine different horizontal-axis wind turbines operating under a wide range of conditions in Europe. The subject turbines covered a broad spectrum of rotor diameters, materials, and operating environments. The final loading sequences were developed as a joint effort of thirteen different European organizations. The goal was to develop a meaningful loading standard for horizontal-axis wind turbine blades that represents common interaction effects seen in service. In 1990, NREL made extensive load measurements on two adjacent Micon 65/13 wind turbines in simultaneous operation in the very turbulent environment of a large wind park. Further, before and during the collection of the loads data, comprehensive measurements of the statistics of the turbulent environment were obtained at both the turbines under test and at two other locations within the park. The trend to larger but lighter wind turbine structures has made an understanding of the expected lifetime loading history of paramount importance. Experience in the US has shown that the turbulence-induced loads associated with multi-row wind parks in general are much more severe than for turbines operating individually or within widely spaced environments. Multi-row wind parks are much more common in the US than in Europe. In this paper we report on our results in applying the methodology utilized to develop the WISPER and WISPERX standardized loading sequences using the available data from the Micon turbines. While the intended purpose of the WISPER sequences were not to represent a specific operating environment, we believe the exercise is useful, especially when a turbine design is likely to be installed in a multi-row wind park. PERFORMANCE OF A STAND-ALONE WIND-ELECTRIC ICE MAKER FOR REMOTE VILLAGES
Holly C. Davis, Michael J. Brandemuehl (Colorado Univ., Boulder, CO.), and Michael L. S. Bergey (Bergey Windpower Co., Inc., Norman, OK.) Jan. 1995 10 p Presented at the 14th American Society of Mechanical Engineers-Energy Sources Technology Conferenceand Exhibition Wind Energy Symposium Houston, TX, 29 Jan. - 1 Feb. 1995
(Contract DE-AC36-83CH-10093)
(DE95-004006; NREL/TP-441-7223; CONF-950116-5) Avail: CASI HC A02/MF A01

Two ice makers in the 1.1 metric tons per 24 hours (1.2 tons per day) size range were tested to determine their performance when directly coupled to a variable-frequency wind turbine generator. Initial tests were conducted using a dynamometer to simulate to wind to evaluate whether previously determined potential problems were significant and to define basic performance parameters. Field testing in Norman, Oklahoma, was completed to determine the performance of one of the ice makers under real wind conditions. As expected, the ice makers produced more ice at a higher speed than rated, and less ice at a lower speed. Due to the large start-up torque requirement of reciprocating compressors, the ice making system experienced a large start-up current and corresponding voltage drop which required a larger wind turbine that expected to provide the necessary current and voltage. Performance curves for ice production and power consumption are presented. A spreadsheet model was constructed to predict ice production at a user-defined site given the wind conditions for that location. Future work should include long-term performance tests and research on reducing the large start-up currents the system experiences when first coming on line. DOE

HEALTH AND ENVIRONMENTAL HAZARDS OF CdTe PHOTOVOLTAIC MODULE PRODUCTION, USE AND DECOMMISSIONING
P. D. Moskowitz, H. Steinberger, and W. Thumm 1995 4 p Presented at the 1st World Conference on Photovoltaic Energy Conversion, Waikoloa, HI, 5-9 Dec. 1994
(Contract DE-AC02-76CH-00016)
(DE95-006688; BNL-61324; CONF-941203-21) Avail: CASI HC A01/MF A01

Health and environmental (H&E) risks presented by CdTe photovoltaic module production, use and decommissioning have been reviewed and discussed by several authors. Several H&E concerns exist. The estimated risks are based on extrapolations of toxicity, environmental mobility, and bioavailability data for other inorganic cadmium compounds. Little information, however, is available about CdTe itself. In response to the increased interest in CdTe, Brookhaven National Laboratory (BNL) has been engaged in a cooperative research program with the National Institute of Environmental Health Sciences (NIEHS), the Fraunhofer Institute for Solid State Technology (IFT), and the GSF Institute of Chemical Ecology to develop fundamental toxicological and environmental data for CdTe. This paper describes the results of these studies, and their potential implications with respect to the H&E hazards presented by CdTe module production, use and decommissioning. DOE

RECENT PROGRESS IN THE PHOTOVOLTAIC MANUFACTURING TECHNOLOGY PROJECT (PVMaT)
C. Edwin Witt, Richard L. Mitchell, Holly Thomas, Lloyd O. Herwig (Department of Energy, Washington, DC.), Douglas S. Ruby (Sandia National Labs., Albuquerque, NM.), and Rick Sellers Dec. 1994 11 p Presented at the 1st World Conference on Photovoltaic Energy Conversion, Waikoloa, HI, 5-9 Dec. 1994 Prepared in cooperation with Sandia National Labs., Albuquerque, NM
(Contract DE-AC36-83CH-10093)
(DE95-000279; NREL/TP-411-7416; CONF-941203-14; SAND-94-3078C) Avail: CASI HC A03/MF A01

The Photovoltaic Manufacturing Technology (PVMaT) Project was initiated in 1990 to help the US photovoltaic (PV) industry extend its world leadership role in manufacturing and commercially developing PV modules and systems. It is being conducted in several phases, staggered to support industry progress. The four most recently awarded subcontracts (Phase 2B) are now completing their first year of research. They include two subcontracts on CdTe, one on Spheral Solar(trademark) Cells, and one on cast polysilicon. These subcontracts represent new technology additions to the PVMaT Project. Subcontracts initiated in earlier phases are nearing completion, and their progress is summarized. An additional phase of PVMaT, Phase 4A, is being initiated which will emphasize product-driven manufacturing research and development. The intention of Phase 4A is to emphasize improvement and cost reduction in the manufacture of full-system PV products. The work areas may include, but are not limited to, issues such as improvement of module manufacturing processes; system and system component packaging, integration, manufacturing, and assembly; product manufacturing flexibility; and balance-of-system development with the goal of product manufacturing improvements. THE US MOLTEN CARBONATE FUEL-CELL DEVELOPMENT AND COMMERCIALIZATION EFFORT
Mark C. Williams, Edward L. Parsons, Jr., and M. J. Mayfield 1995 5 p Presented at the Fuel Cell Seminar, San Diego, CA,28 Nov. - 1 Dec. 1994; sponsored by the Electric Power Research Inst.; the Gas Research Inst.; and the US Department of Energy
(DE95-008580; DOE/METC-C/95/7171; CONF-941109-2) Avail: CASI HC A01/MF A01

The authors discuss the status of molten carbonate fuel-cell (MCFC) development in the US, including the role of the US Department of Energy (DOE) in commercializing MCFC power-plant products for use by gas utility and electric power industries. The authors describe major fundamental stack research issues, as well as MCFC power-plant network and system issues, that need to be resolved before MCFC technology can be commercialized. A significant initiative in MCFC research is the spatial configuration of MCFC stacks into networks in a fuel-cell power plant. DOE

INVESTIGATION OF HIGH-TEMPERATURE SUPERCONDUCTING FLYWHEEL ENERGY STORAGE DEVICES
Mar. 1994 201 p In JAPANESE
(DE95-759242; NEDO-P-9310) Avail: CASI HC A10/MF A03

The paper studies a possibility of the technology of a high-temperature superconducting flywheel energy storage system and extracts its technical subjects. As a result of investigating the present status of technology and development of the flywheel for the electric energy storage system, it is found that it is a promising technology which has basically a wide applicability to multipurposes. A combination of the technology only with the existing element technology is fully feasible, and the system shows excellent performance in energy storage for medium-scale capacity for a relatively short period. However, there have been seen few application examples. For application to power systems and industrial systems, it is necessary to reduce operational loss of the system and to realize flywheels which can store much larger capacities of energy. It is proposed that a combination of high-temperature superconducting bulk and permanent magnet is used for magnetic supporting of the flywheel. Technical problems are also extracted of the high temperature superconducting flywheel system as an energy storage system for load leveling. DOE

INVESTIGATION ON ENERGY CONVERSION TECHNOLOGY USING BIOCHEMICAL REACTION ELEMENTS, 2
Mar. 1994 252 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE95-759250; NEDO-GET-9302-2) Avail: CASI HC A12

For measures taken for resource/energy and environmental issues, a study is made on utilization of microbial biochemical reaction. As a reaction system using chemical energy, cited is production of petroleum substitution substances and food/feed by CO2 fixation using hydrogen energy and hydrogen bacteria. As to photo energy utilization, regarded as promising are CO2 fixation using photo energy and microalgae, and production of hydrogen and useful carbon compound using photosynthetic organisms. As living organism/electric energy interconversion, cited is the culture of chemoautotrophic bacteria which fix CO2 using electric energy. For enhancing its conversion efficiency, it is important to develop a technology of gene manipulation of the bacteria and a system to use functional biochemical elements adaptable to the electrode reaction. With regard to utilization of the microorganism metabolic function, the paper presents emission of soluble nitrogen in the hydrosphere into the atmosphere using denitrifying bacteria, removal of phosphorus, reduction in environmental pollution caused by heavy metal dilute solutions, and recovery as resources, etc. DOE

R and D projects on electricity generating wind turbines were conducted at the NASA Lewis Research Center from 1973 to 1988. Most projects were sponsored by the U.S. Department of Energy (DOE), a major element of its Federal Wind Energy Program. Another large wind turbine project was by the Bureau of Reclamation of the U.S. Department of Interior (DOI). From 1988 to 1995, NASA wind energy activities have been directed toward the transfer of technology to commercial and academic organizations. As part of these technology transfer activities, previously unpublished manuscripts have been assembled and presented here to share the wind turbine research results with the wind energy community. A variety of wind turbine technology topics are discussed: Wind and wake models; Airfoil properties; Structural analysis and testing; Control systems; Variable speed generators; and acoustic noise. Experimental and theoretical results are discussed. For individual titles, see N95-27971 through N95-27992.

BASIC PRINCIPLES AND RECENT OBSERVATIONS OF ROTATIONALLY SAMPLED WIND c47
James R. Connell *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 1-15 (For primary document see N95-27970 09-44)
(Contract DE-AC06-76LR-01830)
Avail: CASI HC A03/MF A03

The concept of rotationally sampled wind speed is described. The unusual wind characteristics that result from rotationally sampling the wind are shown first for early measurements made using an 8-point ring of anemometers on a vertical plane array of meteorological towers. Quantitative characterization of the rotationally sampled wind is made in terms of the power spectral density function of the wind speed. Verification of the importance of the new concept is demonstrated with spectral analyses of the response of the MOD-OA blade flapwise root bending moment and the corresponding rotational analysis of the wind measured immediately upwind of the MOD-OA using a 12-point ring of anemometers on a 7-tower vertical plane array. The Pacific Northwest Laboratory (PNL) theory of the rotationally sampled wind speed power spectral density function is tested successfully against the wind spectrum measured at the MOD-OA vertical plane array. A single-tower empirical model of the rotationally sampled wind speed is also successfully tested against the measurements from the full vertical plane array. Rotational measurements of the wind velocity with hotfilm anemometers attached to rotating blades are shown to be accurate and practical for research on winds at the blades of wind turbines. Some measurements at the rotor blade of a MOD-2 turbine using the hotfilm technique in a pilot research program are shown. They are compared and contrasted to the expectations based upon application of the PNL theory of rotationally sampled wind to the MOD-2 size and rotation rate but without teeter, blade bending, or rotor induction accounted for. Finally, the importance of temperature layering and of wind modifications due to flow over complex terrain is demonstrated by the use of hotfilm anemometer data, and meteorological tower and acoustic doppler sounder data from the MOD-2 site at Goodnoe Hills, Washington. A MODEL OF ROTATIONALLY-SAMPLED WIND TURBULENCE FOR PREDICTING FATIGUE LOADS IN WIND TURBINES c39
David A. Spera *In its* Collected Papers on Wind Turbine Technology May 1995 p 17-26 (For primary document see N95-27970 09-44)
Avail: CASI HC A02/MF A03

Empirical equations are presented with which to model rotationally-sampled (R-S) turbulence for input to structural-dynamic computer codes and the calculation of wind turbine fatigue loads. These equations are derived from R-S turbulence data which were measured at the vertical-plane array in Clayton, New Mexico. For validation, the equations are applied to the calculation of cyclic flapwise blade loads for the NASA/DOE Mod-2 2.5-MW experimental HAWT's (horizontal-axis wind turbines), and the results compared to measured cyclic loads. Good correlation is achieved, indicating that the R-S turbulence model developed in this study contains the characteristics of the wind which produce many of the fatigue loads sustained by wind turbines. Empirical factors are included which permit the prediction of load levels at specified percentiles of occurrence, which is required for the generation of fatigue load spectra and the prediction of the fatigue lifetime of structures. From the theoretical fluid dynamics point of view, the wake region of a large horizontal-axis wind turbine has been defined and described, and numerical models of wake behavior have been developed. Wind tunnel studies of single turbine wakes and turbine array wakes have been used to verify the theory and further refine the numerical models. However, the effects of scaling, rotor solidity, and topography on wake behavior are questions that remain unanswered. In the wind tunnel studies, turbines were represented by anything from scaled models to tea strainers or wire mesh disks whose solidity was equivalent to that of a typical wind turbine. The scale factor compensation for the difference in Reynolds number between the scale model and an actual turbine is complex, and not typically accounted for. Though it is wise to study the simpler case of wakes in flat topography, which can be easily duplicated in the wind tunnel, current indications are that wind turbine farm development is actually occurring in somewhat more complex terrain. Empirical wake studies using large horizontal-axis wind turbines have not been thoroughly composited, and, therefore, the results have not been applied to the well-developed theory of wake structure. The measurement programs have made use of both in situ sensor systems, such as instrumented towers, and remote sensors, such as kites and tethered, balloonborne anemometers. We present a concise overview of the work that has been performed, including our own, which is based on the philosophy that the MOD-2 turbines are probably their own best detector of both the momentum deficit and the induced turbulence effect downwind. Only the momentum deficit aspects of the wake/machine interactions have been addressed. Both turbine power output deficits and wind energy deficits as measured by the onsite meteorological towers have been analyzed from a composite data set. The analysis has also evidenced certain topographic influences on the operation of spatially diverse wind turbines. Author

HORIZONTAL AXIS WIND TURBINE POST STALL AIRFOIL CHARACTERISTICS SYNTHESIZATION c02

James L. Tangler and Cyrus Ostowari (Texas A&M Univ., College Station, TX.) *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 35-39 (For primary document see N95-27970 09-44)

(Contract DE-AC04-76DP-03533)

Avail: CASI HC A01/MF A03

Blade-element/momentum performance prediction codes are routinely used for wind turbine design and analysis. A weakness of these codes is their inability to consistently predict peak power upon which the machine structural design and cost are strongly dependent. The purpose of this study was to compare post-stall airfoil characteristics synthesization theory to a systematically acquired wind tunnel data set in which the effects of aspect ratio, airfoil thickness, and Reynolds number were investigated. The results of this comparison identified discrepancies between current theory and the wind tunnel data which could not be resolved. Other factors not previously investigated may account for these discrepancies and have a significant effect on peak power prediction. Author

PRELIMINARY ANALYSIS OF DYNAMIC STALL EFFECTS ON A 91-METER WIND TURBINE ROTOR c02

Robert E. Wilson *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 41-46 (For primary document see N95-27970 09-44)

Avail: CASI HC A02/MF A03

Analytical investigation of dynamic stall on HAWT (horizontal-axis wind turbines) rotor loads was conducted. Dynamic stall was modeled using the Gormont approach on the MOD-2 rotor, treating the blade as a rigid body teetering about a fixed axis. Blade flapwise bending moments at station 370 were determined with and without dynamic stall for spatial variations in local wind speed due to wind shear and yaw. The predicted mean flapwise bending moments were found to be in good agreement with test results. Results obtained with and without dynamic stall showed no significant difference for the mean flapwise bending moment. The cyclic bending moments calculated with and without dynamic stall effects were substantially the same. None of the calculated cyclic loads reached the level of the cyclic loads measured on the MOD-2 using the Boeing five-minute-average technique. Author

COMPARATIVE WIND TUNNEL TESTS OF NACA 23024 AIRFOILS WITH SEVERAL AILERON AND SPOILER CONFIGURATIONS c02

W. H. Wentz, Jr. and M. H. Snyder *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 47-52 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1994 (For primary document see N95-27970 09-44)

(Grant NsG-3277)

Avail: CASI HC A02/MF A03

This paper reviews research efforts at Wichita State University sponsored by NASA Lewis Research Center to design and evaluate aerodynamic braking devices which will be smaller and lighter than full-chord blade pitch control. Devices evaluated include a variety of aileron configurations, and spoilers located at both trailing edge and near the leading edge. The paper discusses analytical modeling, wind tunnel tests, and for some configurations, full-scale rotor tests. Current designs have not provided adequate control power at high angles of attack (low tip-speed-ratios). The reasons for these limitations are discussed. Analysis and wind tunnel test data indicate that several options are available to the designer to provide aerodynamic slowdown without full-chord pitch control. Three options are suggested; adding venting in front of the control surface hingeline, using spoilers located near the leading edge, and using a two-piece control combining downward deflection inboard with upward deflection outboard. COMPARATIVE WIND TUNNEL TEST AT HIGH REYNOLDS NUMBERS OF NACA 64 621 AIRFOILS WITH TWO AILERON CONFIGURATIONS c02

G. M. Gregorek *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 53-66 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1984 (For primary document see N95-27970 09-44)

(Grant NAG3-330)

Avail: CASI HC A03/MF A03

An experimental program to measure the aerodynamic characteristics of the NACA 64-621 airfoil when equipped with plain ailerons of 0.38 chord and 0.30 chord and with 0.38 chord balanced aileron has been conducted in the pressurized O.S.U. 6 x 12 ft High Reynolds Number Wind Tunnel. Surface pressures were measured and integrated to yield lift and pressure drag coefficients for angles of attack from -3 to +42 deg and for selected aileron deflections from 0 to -90 deg at nominal Mach and Reynolds numbers of 0.25 and 5 x 10(exp 6). When resolved into thrust coefficient for wind turbine aerodynamic control applications, the data indicated the anticipated decrease in thrust coefficient with negative aileron deflection at low angles of attack; however, as angle of attack increased, thrust coefficients eventually became positive. All aileron configurations, even at -90 deg deflections showed this trend. Hinge moments for each configuration complete the data set. Author

COMPARATIVE PERFORMANCE TESTS ON THE Mod-2, 2.5-mW WIND TURBINE WITH AND WITHOUT VORTEX GENERATORS c02

G. E. Miller *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 67-77 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1984 (For primary document see N95-27970 09-44)

Avail: CASI HC A03/MF A03

A test program was conducted on the third Mod-2 unit at Goldendale, Washington, to systematically study the effect of vortex generators (VG's) on power performance. The subject unit was first tested without VG's to obtain baseline data. Vortex generators were then installed on the mid-blade assemblies, and the resulting 70% VG configuration was tested. Finally, vortex generators were mounted on the tip assemblies, and data was recorded for the 100% VG configuration. This test program and its results are discussed in this paper. The development of vortex generators is also presented. Author

DESIGN OF A REAL-TIME WIND TURBINE SIMULATOR USING A CUSTOM PARALLEL ARCHITECTURE c61

John A. Hoffman, R. Gluck (TRW Space Technology Labs., Redondo Beach, CA.), and S. Sridhar (TRW Space Technology Labs., Redondo Beach, CA.) *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 79-87 Sponsored by DOE (For primary document see N95-27970 09-44)

Avail: CASI HC A02/MF A03

The design of a new parallel-processing digital simulator is described. The new simulator has been developed specifically for analysis of wind energy systems in real time. The new processor has been named: the Wind Energy System Time-domain simulator, version 3 (WEST-3). Like previous WEST versions, WEST-3 performs many computations in parallel. The modules in WEST-3 are pure digital processors, however. These digital processors can be programmed individually and operated in concert to achieve real-time simulation of wind turbine systems. Because of this programmability, WEST-3 is very much more flexible and general than its two predecessors. The design features of WEST-3 are described to show how the system produces high-speed solutions of nonlinear time-domain equations. WEST-3 has two very fast Computational Units (CU's) that use

minicomputer technology plus special architectural features that make them many times faster than a microcomputer. These CU's are needed to perform the complex computations associated with the wind turbine rotor system in real time. The parallel architecture of the CU causes several tasks to be done in each cycle, including an IO operation and the combination of a multiply, add, and store. The WEST-3 simulator can be expanded at any time for additional computational power. This is possible because the CU's interfaced to each other and to other portions of the simulation using special serial buses. These buses can be 'patched' together in essentially any configuration (in a manner very similar to the programming methods used in analog computation) to balance the input/ output requirements. CU's can be added in any number to share a given computational load. This flexible bus feature is very different from many other parallel processors which usually have a throughput limit because of rigid bus architecture.

A NASTRAN-BASED COMPUTER PROGRAM FOR STRUCTURAL DYNAMIC ANALYSIS OF HORIZONTAL AXIS WIND TURBINES **c39**
Don W. Lobitz *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 89-97 Sponsored by DOE (For primary document see N95-27970 09-44)
(Contract DE-AC04-76DP-00789)
Avail: CASI HC A02/MF A03

This paper describes a computer program developed for structural dynamic analysis of horizontal axis wind turbines (HAWT's). It is based on the finite element method through its reliance on NASTRAN for the development of mass, stiffness, and damping matrices of the tower end rotor, which are treated in NASTRAN as separate structures. The tower is modeled in a stationary frame and the rotor in one rotating at a constant angular velocity. The two structures are subsequently joined together (external to NASTRAN) using a time-dependent transformation consistent with the hub configuration. Aerodynamic loads are computed with an established flow model based on strip theory. Aeroelastic effects are included by incorporating the local velocity and twisting deformation of the blade in the load computation. The turbulent nature of the wind, both in space and time, is modeled by adding in stochastic wind increments. The resulting equations of motion are solved in the time domain using the implicit Newmark-Beta integrator. Preliminary comparisons with data from the Boeing/NASA MOD2 HAWT indicate that the code is capable of accurately and efficiently predicting the response of HAWT's driven by turbulent winds.

AEROELASTIC STABILITY OF WIND TURBINE BLADE/AILERON SYSTEMS **c02**
J. C. Strain and L. Mirandy (General Electric Co., Schenectady, NY.) *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 99-114 (For primary document see N95-27970 09-44)
(Contract DEN3-153)
Avail: CASI HC A03/MF A03

Aeroelastic stability analyses have been performed for the MOD-5A blade/aileron system. Various configurations having different aileron torsional stiffness, mass unbalance, and control system damping have been investigated. The analysis was conducted using a code recently developed by the General Electric Company - AILSTAB. The code extracts eigenvalues for a three degree of freedom system, consisting of: (1) a blade flapwise mode; (2) a blade torsional mode; and (3) an aileron torsional mode. Mode shapes are supplied as input and the aileron can be specified over an arbitrary length of the blade span. Quasi-steady aerodynamic strip theory is used to compute aerodynamic derivatives of the wing-aileron combination as a function of spanwise position. Equations of motion are summarized herein. The program provides rotating blade stability boundaries for torsional divergence, classical flutter (bending/torsion) and wing/aileron flutter. It has been checked out against fixed-wing results published by Theodorsen and Garrick. The MOD-5A system is stable with respect to divergence and classical flutter for all practical rotor speeds. Aileron torsional stiffness must exceed a minimum critical value to prevent aileron flutter. The nominal control system stiffness greatly exceeds this minimum during normal operation. The basic system, however, is unstable for the case of a free (or floating) aileron. The instability can be removed either by the addition of torsional damping or mass-balancing the ailerons. The MOD-5A design was performed by the General Electric Company, Advanced Energy Program Department under Contract DEN3-153 with NASA Lewis Research Center and sponsored by the Department of Energy.

CALCULATION OF DESIGN LOAD FOR THE MOD-5A 7.3 mW WIND TURBINE SYSTEM **c39**
L. Mirandy and J. C. Strain *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 115-138a (For primary document see N95-27970 09-44)
(Contract DEN3-153)
Avail: CASI HC A03/MF A03

Design loads are presented for the General Electric MOD-SA wind turbine. The MOD-SA system consists of a 400 ft. diameter, upwind, two-bladed, teetered rotor connected to a 7.3 mW variable-speed generator. Fatigue loads are specified in the form of histograms for the 30 year life of the machine, while limit (or maximum) loads have been derived from transient dynamic analysis at critical operating conditions. Loads prediction was accomplished using state of the art aeroelastic analyses developed at General Electric. Features of the primary predictive tool - the Transient Rotor Analysis Code (TRAC) are described in the paper. Key to the load predictions are the following wind models: (1) yearly mean wind distribution; (2) mean wind variations during operation; (3) number of start/shutdown cycles; (4) spatially large gusts; and (5) spatially small gusts (local turbulence). The methods used to develop statistical distributions from load calculations represent an extension of procedures used in past wind programs and are believed to be a significant contribution to Wind Turbine Generator analysis. Test/theory correlations are presented to demonstrate code load predictive capability and to support the wind models used in the analysis. In addition MOD-5A loads are compared with those of existing machines. The MOD-5A design was performed by the General Electric Company, Advanced Energy Program Department, under Contract DEN3-153 with NASA Lewis Research Center and sponsored by the Department of Energy.

COMPARISON OF MEASURED AND CALCULATED DYNAMIC LOADS FOR THE Mod-2 2.5 mW WIND TURBINE SYSTEM **c39**
D. K. Zimmerman, S. A. Shipley, and R. D. Miller *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 139-152 (For primary document see N95-27970 09-44)
Avail: CASI HC A03/MF A03

The Boeing Company, under contract to the Electric Power Research Institute (EPRI), has completed a test program on the Mod-2 wind turbines at Goodnoe Hills, Washington. The objectives were to update fatigue load spectra, discern site and machine differences, measure vortex generator effects, and to evaluate rotational sampling techniques. This paper shows the test setup and loads instrumentation, loads data comparisons and test/analysis correlations. Test data are correlated with DYLOSAT predictions using both the NASA interim turbulence model and rotationally sampled winds as inputs. The latter is demonstrated to have the potential to improve the test/analysis correlations. The paper concludes with an assessment of the importance of vortex generators, site dependence, and machine differences on fatigue loads. The adequacy of prediction techniques used are evaluated and recommendations are made for improvements to the methodology.

ANALYSIS METHODS FOR WIND TURBINE CONTROL AND ELECTRICAL SYSTEM DYNAMICS **c33**
E. N. Hinrichsen *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 153-156 (For primary document see N95-27970 09-44)
Avail: CASI HC A01/MF A03

The integration of new energy technologies into electric power systems requires methods which recognize the full range of dynamic events in both the new generating unit and the power system. Since new energy technologies are initially perceived as small contributors to large systems, little attention is generally paid to system integration, i.e. dynamic events in the power system are ignored. As a result, most new energy sources are only capable of base-load operation, i.e. they have no load following or cycling capability. Wind turbines are no exception. Greater awareness of this implicit (and often unnecessary) limitation is needed. Analysis methods are recommended which include very low penetration (infinite bus) as well as very high penetration (stand-alone) scenarios. Author

CONTROL SYSTEM DESIGN FOR THE MOD-5A 7.3 mW WIND TURBINE GENERATOR **c37**

Robert S. Barton, Theodore J. Hosp, and George P. Schanzenbach *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 157-174 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1984 (For primary document see N95-27970 09-44)
(Contract DEN3-153)
Avail: CASI HC A03/MF A03

This paper provides descriptions of the requirements analysis, hardware development and software development phases of the Control System design for the MOD-5A 7.3 mW Wind Turbine Generator. The system, designed by General Electric Company, Advanced Energy Programs Department, under contract DEN 3-153 with NASA Lewis Research Center and DOE, provides real time regulation of rotor speed by control of both generator torque and rotor torque. A variable speed generator system is used to provide both airgap torque control and reactive power control. The wind rotor is designed with segmented ailerons which are positioned to control blade torque. The central component of the control system, selected early in the design process, is a programmable controller used for sequencing, alarm monitoring, communication, and real time control. Development of requirements for use of aileron controlled blades and a variable speed generator required an analytical simulation that combined drivetrain, tower and blade elastic modes with wind disturbances and control behavior. An orderly two phase plan was used for controller software development. A microcomputer based turbine simulator was used to facilitate hardware and software integration and test. Author

W. A. Blissell, Jr. *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 175-1190 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1984 Sponsored by DOE (For primary document see N95-27970 09-44)
(Contract DEN3-153)
Avail: CASI HC A02/MF A03

The Control System for the Mod-2 wind turbine system is required to provide not only for startup, RPM regulation, maximizing or regulating power, and stopping the rotor, but also for load limiting, especially in the power train. Early operations with above-rated winds revealed an instability which was caused primarily by coupling between the quill shaft and the rotor air loads. This instability caused the first of several major Mod-2 Control System changes which are reviewed in the paper. Author

Robert S. Barton *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 199-210 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1984 (For primary document see N95-27970 09-44)
Avail: CASI HC A03/MF A03

This paper describes the application of a Scherbiustat type variable speed subsystem in the MOD-5A Wind Turbine Generator. As designed by General Electric Company, Advanced Energy Programs Department, under contract DEN3-153 with NASA Lewis Research Center and DOE, the MOD-5A utilizes the subsystem for both starting assistance in a motoring mode and generation in a controlled airgap torque mode. Reactive power control is also provided. The Scherbiustat type arrangement of a wound rotor machine with a cycloconverter in the rotor circuit was selected after an evaluation of variable speed technologies that followed a system evaluation of drivetrain cost and risk. The paper describes the evaluation factors considered, the results of the evaluations and summarizes operating strategy and performance simulations. Author

MEASUREMENT AND PREDICTION OF BROADBAND NOISE FROM LARGE HORIZONTAL AXIS WIND TURBINE GENERATORS **c71**

F. W. Grosveld, K. P. Shepherd, and H. H. Hubbard (College of William and Mary, Williamsburg, VA.) *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 211-220 (For primary document see N95-27970 09-44)
Avail: CASI HC A02/MF A03

A method is presented for predicting the broadband noise spectra of large wind turbine generators. It includes contributions from such noise sources as the inflow turbulence to the rotor, the interactions between the turbulent boundary layers on the blade surfaces with their trailing edges and the wake due to a blunt trailing edge. The method is partly empirical and is based on acoustic measurements of large wind turbines and airfoil models. Spectra are predicted for several large machines including the proposed MOD-5B. Measured data are presented for the MOD-2, the WTS-4, the MOD-OA, and the U.S. Windpower Inc. machines. Good agreement is shown between the predicted and measured far field noise spectra. Author

OBSERVED ACOUSTIC AND AEROELASTIC SPECTRAL RESPONSES OF A MOD-2 TURBINE BLADE TO TURBULENCE EXCITATION **c71**

N. D. Kelley, H. E. McKenna, and E. W. Jacobs *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 221-227 (For primary document see N95-27970 09-44)
(Contracts DE-AC02-83CH-10093; EG-77-C-01-4042)
Avail: CASI HC A02/MF A03

Early results from a recent experiment designed to directly evaluate the aeroacoustic/elastic spectral responses of a MOD-2 turbine blade to turbulence-induced unsteady blade loads are discussed. The experimental procedure consisted of flying a hot-film anemometer from a tethered balloon in the turbine inflow and simultaneously measuring the fluctuating airload and aeroelastic response at two blade span stations (65% and 87% spans) using surface-mounted, subminiature pressure transducers and standard strain gage instrumentation. The radiated acoustic pressure field was measured with a triad of very-low-frequency microphones placed at ground level, 1.5 rotor diameters upwind of the disk. Initial transfer function estimates for acoustic radiation, blade normal forces, flapwise acceleration/displacement, and chord/flapwise moments are presented. Author

ANECHOIC WIND TUNNEL STUDY OF TURBULENCE EFFECTS ON WIND TURBINE BROADBAND NOISE **c71**
B. Loyd and W. L. Harris *In* DASCON Engineering, Collected Papers on Wind Turbine Technology May 1995 p 229-236 Presented at the DOE/NASA Workshop on Horizontal Axis Wind Turbine Technology, Cleveland, OH, 8-10 May 1984 (For primary document see N95-27970 09-44)
(Grant NAG3-378)
Avail: CASI HC A02/MF A03

This paper describes recent results obtained at MIT on the experimental and theoretical modelling of aerodynamic broadband noise generated by a downwind rotor horizontal axis wind turbine. The aerodynamic broadband noise generated by the wind turbine rotor is attributed to the interaction of ingested turbulence with the rotor blades. The turbulence was generated in the MIT anechoic wind tunnel facility with the aid of biplanar grids of various sizes. The spectra and the intensity of the aerodynamic broadband noise have been studied as a function of parameters which characterize the turbulence and of wind turbine performance parameters. Specifically, the longitudinal integral scale of turbulence, the size scale of turbulence, the number of turbine blades, and free stream velocity were varied. Simultaneous measurements of acoustic and turbulence signals were made. The sound pressure level was found to vary directly with the integral scale of the ingested turbulence but not with its intensity level. A theoretical model based on unsteady aerodynamics is proposed. Author

GEOTHERMAL DEVELOPMENT IN AUSTRALIA
K. L. Burns, R. A. Creelman, N. W. Buckingham, and H. J. Harrington 1995 8 p Presented at the World Geothermal Congress: Worldwide Utilization of Geothermal Energy, Florence, Italy, 18-31 May 1995
(Contract W-7405-eng-36)
(DE95-007837; LA-UR-95-775; CONF-950514-9) Avail: CASI HC A02/MF A01

In Australia, natural hot springs and hot artesian bores have been developed for recreational and therapeutic purposes. A district heating system at Portland, in the Otway Basin of western Victoria, has provided uninterrupted service for 12 Sears without significant problems, is servicing a building area of 18 990 sq m, and has prospects of expansion to manufacturing uses. A geothermal well has provided hot water for paper manufacture at Traralgon, in the Gippsland Basin of eastern Victoria. Power production from hot water aquifers was tested at Mulka in South Australia, and is undergoing a four-year production trial at Birdsville in Queensland. An important Hot Dry Rock resource has been confirmed in the Cooper Basin. It has been proposed to build an HDR experimental facility to test power production from deep conductive resources in the Sydney Basin near Muswellbrook. DOE

REVIEW AND ANALYSIS OF THE 1980-1989 BIOMASS THERMOCHEMICAL CONVERSION PROGRAM
D. J. Stevens Sep. 1994 274 p
(Contract DE-AC36-83CH-10093)
(DE95-000287; NREL/TP-421-7501) Avail: CASI HC A12/MF A03

In the period between 1980 and 1989, the U.S. Department of Energy (DOE) sponsored research and development projects through its Biomass Thermochemical Conversion (BTC) Program. Thermochemical conversion technologies use elevated temperatures to convert biomass into more useful forms of energy such as fuel gases or transportation fuels. The BTC Program included a wide range of biomass conversion projects in the areas of gasification, pyrolysis, liquefaction, and combustion. This work formed the basis of the present DOE research and development efforts on advanced liquid fuel and power generation systems. At the beginning of Fiscal Year 1989, the management of the BTC Program was transferred from Pacific Northwest Laboratory (PNL) to National Renewable Energy Laboratory (NREL, formerly Solar Energy Research Institute). This document presents a summary of the research which was performed under the BTC Program during the 1981-1989 time frame. The document consists of an analysis of the research projects which were funded by the BTC Program and a bibliography of published documents. This work will help ensure that information from PNL's BTC Program is available to those interested in biomass conversion technologies. The background of the BTC Program is discussed in the first chapter of this report. In addition, a brief summary of other related biomass research and development programs funded by the U.S. Department of Energy and others is presented with references where additional information can be found. The remaining chapters of the report present a detailed summary of the research projects which were funded by the BTC Program. The progress which was made on each project is summarized, the overall impact on biomass conversion is discussed, and selected references are provided. DOE

THE U.S. DEPARTMENT OF ENERGY WIND TURBINE DEVELOPMENT PROGRAM
H. Link, A. Laxson, B. Smith, and P. Goldman (Department of Energy, Washington, DC.) Mar. 1995 9 p Presented at the American Society of Mechanical Engineers/Japanese Society of Mechanical Engineers/Japan Solar Energy Society International Solar Energy Conference, Lahaina, HI, 19-24 Mar. 1995
(Contract DE-AC36-83CH-10093)
(DE95-000292; NREL/TP-441-7390; CONF-950336-20) Avail: CASI HC A02/MF A01

The development of technologically-advanced wind turbines continues to be a high priority of the US wind industry. The United States Department of Energy (DOE) is sponsoring a range of projects that assist the wind industry to design, develop, and test new wind turbines. The overall goal is to develop turbines that can compete with conventional electric generation with a cost of energy (COE) of 5 cents/kWh at 5.8 m/s (13 mph sites) by the mid-1990s and with a cost of energy of 4 cents/kWh or less at 5.8 m/s sites by the year 2000. These goals will be supported through the DOE Turbine Development Program. The Turbine Development Program uses a two-path approach. The first path assists US industry to develop and integrate innovative technologies into utility-grade wind turbines for the near-term (mid-1990s). The second path assists industry to develop a new generation of turbines for the year 2000. This paper describes present and planned projects under the Turbine Development Program. DOE

BUILDING-INTEGRATED PHOTOVOLTAICS: A CASE STUDY
G. Kiss, J. Kinkead, and M. Raman Mar. 1995 139 p
(Contract DE-AC36-83CH-10093)
(DE95-004032; NREL/TP-472-7574) Avail: CASI HC A07/MF A02

In 1992, Kiss Cathcart Anders Architects performed a study for NREL on Building-Integrated Photovoltaics (BIPV) issues as seen from the perspective of the building community. In general, the purpose of the study was to list major issues and potential applications; by it's nature it asked more questions than it answered. This second phase study was to produce quantitative data on the performance of specific BIPV systems. Only roof systems are evaluated. The energy performance, construction cost and simple payback for five different BIPV roof options are evaluated in six different locations: Oakland, New York, Miami, Phoenix, Chicago, and Cincinnati. The roof options evaluated include the following: single-glazed PV roof using glass-substrate PVs; double-glazed PV roof with insulating PV modules; ballasted roof-mounted system; sawtooth light monitor roof with indirect north daylighting; sawtooth roof with north light and active heat recovery. Development of analytical and functional guidelines to help researchers and technicians engaged in interdisciplinary research to better plan and implement their supporting data management activities is addressed. An emphasis is on the projects that involve both geophysical and ecological issues. Six case studies were used to identify and to understand problems associated with collecting, integrating, and analyzing environmental data from local to global spatial scales and over a range of temporal scales. These case studies were also used to elaborate the common barriers to interfacing data of disparate sources and types. A number of lessons derived from the case studies are summarized and analyzed.

NONLINEAR DYNAMICS OF GLOBAL ATMOSPHERIC AND EARTH SYSTEM PROCESSES Final Report, 15 Jul. 1993 - 15 Jan. 1995
Taiping Zhang (Yale Univ., New Haven, CT.), Mikhail Verbitsky (Yale Univ., New Haven, CT.), Barry Saltzman (Yale Univ., New Haven, CT.), Michael E. Mann (Yale Univ., New Haven, CT.), Jeffrey Park (Yale Univ., New Haven, CT.), and Upmanu Lall (Utah State Univ., Logan, UT.) 15 Jan. 1995 8 p
(Grant NAG5-2316)
(NASA-CR-197926; NAS 1.26:197926) Avail: CASI HC A02/MF A01

During the grant period, the authors continued ongoing studies aimed at enhancing their understanding of the operation of the atmosphere as a complex nonlinear system interacting with the hydrosphere, biosphere, and cryosphere in response to external radiative forcing. Five papers were completed with support from the grant, representing contributions in three main areas of study: (1) theoretical studies of the interactive atmospheric response to changed biospheric boundary conditions measurable from satellites; (2) statistical-observational studies of global-scale temperature variability on interannual to century time scales; and (3) dynamics of long-term earth system changes associated with ice sheet surges. [FLOW CYTOMETRY AS A MEANS OF DETECTING, ENUMERATING AND CHARACTERIZING BACTERIA FOR MONITORING OF THE ENVIRONMENT] Quarterly Report, 8 Jan. - 11 Mar. 1994
1994 5 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N68171-94-C-9101)
(AD-A288997; R/D-7186-CN-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The general purpose of the present project is to evaluate flow cytometry as a means of detecting, enumerate and characterize bacteria harvested from air and water samples as part of a system for continuous monitoring of the environment with regard to potentially harmful organisms. In this initial phase of the project we have, in accordance with the project proposal, concentrated on the aspect of detection and enumeration of bacteria, using as a model a variety of species grown in culture. When bacteria are measured for monitoring purposes it is preferable to work with vital unfixed cells, partly to save time and partly because fixation of cells may cause aggregation, and also mask phenomena associated with vital functions, including the very aspect of vital versus dead. Thus, much of our effort has been directed towards development of staining procedures for unfixed samples. In order to establish such procedures, screening experiments with different fluorescent dyes were necessary. The emphasis has been primarily on the effects of different buffers and temperature as means of permeabilizing the cell wall sufficiently to admit the dyes used, but not enough to facilitate efflux of macromolecules. Flow cytometry (FCM) is a technique for measuring the fluorescence and the light scattering of individual cells in large numbers. The cells are measured as they flow in a fluid stream one by one through the focus of an intense light source. The fluorescence intensity (FL) is (usually) proportional to the cellular content of the fluorescent substance(s). Most FCM's can measure two or more fluorescence wavelength components simultaneously, thus facilitating the staining of cells with two or more different dyes. DTIC

Environmental pollution is among the major issues highlighted in many discussion between the Government and Non-Government officials whether in the developed or developing countries. The problems becoming worsen when not many people are concerned on its detrimental effects on the future generations. The increasing number of forest activities without proper replanting will also expose to flood problems, soil erosion, landslides and many more as results of environmental impacts. The urbanization process, couple with the rapid industrial development, without having proper planning and inadequate pollutions control, may also create a long term disasters. Penang island territory has been experiencing the most highly physical development growth in this country. Hence, environmental problems are becoming the major issues. This paper will discuss on the various environmental problem, particularly in Penang and possible remedials to be taken by the state and federal authority to overcome the problems. The type of pollutions such as air and water pollutions, acid rain and of course the reduction of ozone layer. Besides that the increase of heat in our climate will also be of our concern in the process of urbanization.

ANALYSIS OF MAGNETIC FIELD LEVELS AT KSC Final Report
Christos G. Christodoulou 5 Aug. 1994 156 p

(Grant NAG10-0126)
(NASA-CR-197678; NAS 1.26:197678; KSC-DF-3772) Avail: CASI HC A08/MF A02

The scope of this work is to evaluate the magnetic field levels of distribution systems and other equipment at Kennedy Space Center (KSC). Magnetic fields levels in several operational areas and various facilities are investigated. Three dimensional mappings and contour are provided along with the measured data. Furthermore, the portion of magnetic fields generated by the 60 Hz fundamental frequency and the portion generated by harmonics are examined. Finally, possible mitigation techniques for attenuating fields from electric panels are discussed. Derived from text

COMPARATIVE EXPERIMENTAL STUDY OF PIXE AND X-RAY FLUORESCENCE ANALYSIS Ph.D. Thesis [ESTUDIO EXPERIMENTAL COMPARATIVO DE LAS TECNICAS PIXE Y XRF]

Luis Ricardo delaVegaBallesteros 1994 92 p In SPANISH
(DE95-607868; INIS-mf-14394) Avail: CASI HC A05/MF A01 (US Sales Only)

PIXE and X RF techniques are powerful analysis instruments in the determination of traces of elements. Although the physical processes characteristic X-rays production (ionization-emission) are similar in both methods, the representative background of each technique, responsible of its sensitivity, are different. This is because the interaction between exciter agents and the matter produces different effects. In PIXE, the background is caused by the radiation produced by the braking of the secondary electrons: Bremsstrahlung. In X RF, the background is due to the elastic and inelastic scattering of photons: Rayleigh and Compton effects. In this work, we have compared the results of the analysis of environmental samples using both methods, in order to know the scope of each one and develop them as complementary techniques. DOE

COMMUNITY RELATIONS PLAN: GALENA AIRPORT AND CAMP ION AIR FORCE STATION, ALASKA Final Report

11 Nov. 1994 55 p
(Contract F33615-90-D-4013)
(AD-A286722; RAD-93-269-107-12-01) Avail: CASI HC A04/MF A01

The U.S. Air Force has been designated as the lead government agency in cleanup efforts at Gelena Airport and Campion Air Force Station, Alaska. This community relations plan (CRP) is consistent with federal guidance for community relations efforts and satisfies the policies established for Superfund remedial activities by the EPA, under direction of the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980, as amended by the Superfund Amendments and Reauthorization Act (SARA) of 1986. The objectives of the CRP are to: Assess community concerns regarding planned and ongoing studies, and determine how and when the public would like to be involved in the decision-making process; Establish procedures for accurate and timely release of information to potentially affected and interested citizen groups, elected officials, public interest groups, agency officials, and the media; Establish methods to facilitate communication between the Air Force and the community at large; Articulate and clarify key issues for the public; Be responsive to the needs and concerns of public interest groups, agency officials, and the media; Receive and understand all the information that the various interest groups have to communicate; and Search for a consensus of the decisions that are being developed throughout the process. PARALLEL ALGORITHMS FOR SEMI-LAGRANGIAN TRANSPORT IN GLOBAL ATMOSPHERIC CIRCULATION MODELS

J. B. Drake, P. H. Worley, J. Michalakes (Argonne National Lab., IL.), and I. T. Foster (Argonne National Lab., IL.) 1995 6 p Presented at the 7th Society for Industrial and Applied Mathematics (SIAM) Conference on Parallel Processing for Scientific Computing, San Francisco, CA, 15-17 Feb. 1995
(Contracts DE-AC05-84OR-21400; W-31-109-eng-38)
(DE95-007385; CONF-950212-6) Avail: CASI HC A02/MF A01

Global atmospheric circulation models (GCM) typically have three primary algorithmic components: columnar physics, spectral transform, and semi-Lagrangian transport. In developing parallel implementations, these three components are equally important and can be examined somewhat independently. A two-dimensional horizontal data decomposition of the three-dimensional computational grid leaves all physics computations on processor, and the only efficiency issues arise in load balancing. A recently completed study by the authors of different approaches to parallelizing the spectral transform showed several viable algorithms. Preliminary results of an analogous study of algorithmic alternatives for parallel semi-Lagrangian transport are described here. DOE

INTEGRATED ASSESSMENT AND THE RELATION BETWEEN LAND-USE CHANGE AND CLIMATE CHANGE

V. H. Dale Oct. 1994 3 p Presented at the 2nd US/Japan Workshop on Global Change Modeling and Assessment: Improving Methodologies and Strategies, Honolulu, HI, 24-27 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE95-006533; CONF-9410306-1) Avail: CASI HC A01/MF A01

Integrated assessment is an approach that is useful in evaluating the consequences of global climate change. Understanding the consequences requires knowledge of the relationship between land-use change and climate change. Methodologies for assessing the contribution of land-use change to atmospheric CO2 concentrations are considered with reference to a particular case study area: south and southeast Asia. The use of models to evaluate the consequences of climate change on forests must also consider an assessment approach. Each of these points is discussed in the following four sections. DOE

COUPLED CHEMISTRY/CLIMATE ISSUES

D. A. Rotman and D. J. Wuebbles (Illinois Univ., Urbana, IL.) Sep. 1994 6 p
(Contract W-7405-eng-48)
(DE95-006443; UCRL-ID-118434) Avail: CASI HC A02/MF A01

Driven by both natural and anthropogenic causes, the distributions of trace chemical species in the atmosphere has altered the natural state of the chemical distribution and, the authors believe, the climate system. A clear example of this change and its effect on climate is through tropospheric ozone. Evidence shows that over the last decade tropospheric ozone has increased, probably caused by increasing concentrations and emissions of CH4, CO, NO(x), and NMHC's (nonmethane hydrocarbons). Tropospheric ozone is photochemically produced when nitrogen oxides react in the presence of carbon monoxide, methane, non-methane hydrocarbons and sunlight. The chemistry of ozone and NO(x) isalso closely associated with the hydroxyl radical (OH), which governs the atmospheric lifetime of a number of species, including CH4 and chlorofluorocarbons (CFC's), which are major greenhouse gases and which affect the chemical balance of the stratosphere. Increases in the concentrations of CO and CH4 can lead to decreased concentrations of OH and a positive feedback on the atmospheric lifetimes of CO and methane. The same would occur for other greenhouse gases and for some of the important reactions which form aerosols in the troposphere. This would further enhance the concentrations of the gases and accelerate the radiative effects from these greenhouse species, strongly affecting climate and the accurate prediction of climate. It is believed that warmer climates will also increase the amount of water in the atmosphere, thereby providing another chemistry feedback on OH. DOE

REDUCING COLD-START EMISSIONS BY CATALYTIC CONVERTER THERMAL MANAGEMENT

S. D. Burch, T. F. Potter, M. A. Keyser, M. J. Brady (Chrysler Corp., Detroit, MI.), and K. F. Michaels (Chrysler Corp., Detroit, MI.) Jan. 1995 6 p Presented at the Society of Automotive Engineers International Congress and Exposition, Detroit, MI, 27 Feb. - 2 Mar. 1995
(Contract DE-AC36-83CH-10093)
(DE95-000256; NREL/TP-473-7025; CONF-950256-3) Avail: CASI HC A02/MF A01

Vacuum insulation and phase-change thermal storage have been used to enhance the heat retention of a prototype catalytic converter. Storing heat in the converter between trips allows exhaust gases to be converted more quickly, significantly reducing cold-start emissions. Using a small metal hydride, the thermal conductance of the vacuum insulation can be varied continuously between 0.49 and 27 W/sq m.k (R-12 to R-0.2 insulation) to prevent overheating of the catalyst. A prototype was installed in a Dodge Neon with a 2.0-liter engine. Following a standard preconditioning and a 23-hour cold soak, an FTP (Federal Test Procedure) emissions test was performed. Although exhaust temperatures during the preconditioning were not hot enough to melt the phase-change material, the vacuum insulation performed well, resulting in a converter temperature of 146 C after the 23-hour cold soak at 27 C. Compared to the same converter at ambient conditions, overall emissions of CO and HC were reduced by 52% and 29%, to 0.27 and 0.037 g/mile, respectively. The maximum converter temperature during the FTP cycle was 720 C. This limited testing was performed with a nearly-fresh palladium-only catalyst, but demonstrates the potential of this vacuum insulation approach for emissions reduction and thermal control. Further testing is ongoing. An initial assessment of several production issues is made, including high-volume fabrication challenges, durability, and cost. DOE

THE PCMDI VISUALIZATION AND COMPUTATION SYSTEM (VCS): A WORKBENCH FOR CLIMATE DATA DISPLAY AND ANALYSIS

Dean N. Williams and Robert L. Mobley Mar. 1994 107 p
(Contract W-7405-eng-48)
(DE95-008586; UCRL-ID-116890) Avail: CASI HC A06/MF A02

This software was developed by the Program for Climate Model Diagnosis and Intercomparison (PCMDI) at the Lawrence Livermore National Laboratory in Livermore, California. It was designed to provide some of the basic capabilities needed for validating, comparing, and diagnosing climate model behavior. It can be controlled either interactively, or from a script file, or control can alternate between these modes during a session. A script can be saved during an interactive session and merely replayed, or it can be edited and replayed. The state-of-the-system can be dumped, as a script, at any instant, and that script can be used later to restore that instant of the session. Attributes for data can describe variables existing in a file or variables to be computed as a function of previously selected variables. The dimensions of variables can be subset, reversed, transposed, wrapped-around, and thinned by selecting either a stride of nodes or by randomly selecting individual nodes. Grid transformations are supported by allowing a different set of dimension vectors to be specified in the dimension descriptors. A display page can be output as either Adobe PostScript for hardcopy, or as a raster image for hardcopy or animation. DOE

ENGINEERING PHOTOCHEMICAL SMOG THROUGH CONVECTION TOWERS

S. Elliott, M. L. Prueitt, J. E. Bossert, E. J. Mroz, R. A. Krakowski, R. L. Miller, M. Z. Jacobson, and R. P. Turco Feb. 1995 35 p
(Contract W-7405-eng-36)
(DE95-007727; LA-12762-MS) Avail: CASI HC A03/MF A01

Reverse convection towers have attracted attention as a medium for cleansing modern cities. Evaporation of an aqueous mist injected at the tower opening could generate electrical power by creating descent, and simultaneously scavenge unsightly and unhealthful particulates. The study offered here assesses the influence to tower water droplets on the photochemical component of Los Angeles type smog. The primary radical chain initiator OH is likely removed into aqueous phases well within the residence time of air in the tower, and then reacts away rapidly. Organics do not dissolve, but nighttime hydrolysis of N2O5 depletes the nitrogen oxides. A lack of HOx would slow hydrocarbon oxidation and so also ozone production. Lowering of NOx would also alter ozone production rates, but the direction is uncertain. SO2 is available in sufficient quantities in some urban areas to react with stable oxidants, and if seawater were the source of the mist, the high pH would lead to fast sulfur oxidation kinetics. With an accommodation coefficient of 10(exp -3), however, ozone may not enter the aqueous phase efficiently. Even if ozone is destroyed or its production suppressed, photochemical recovery times are on the order of hours, so that tower processing must be centered on a narrow midday time window. The cost of building the number of structures necessary for this brief turnover could be prohibitive. The increase in humidity accompanying mist evaporation could be controlled with condensers, but might otherwise counteract visibility enhancements by recreating aqueous aerosols. Quantification of the divergent forcings convection towers must exert upon the cityscape would call for coupled three dimensional modeling of transport, microphysics, and photochemistry. DOE

CALCULATIONS OF DOWNWARD IR SURFACE FLUXES IN THE 500-3,000 cm(EXP -1) WAVENUMBER RANGE FOR THE 1994 ICRCCM MODEL INTERCOMPARISON STUDY

Allen S. Grossman, Keith E. Grant, and Ted Bakowsky Sep. 1994 16 p Sponsored in part by the DOE's Domestic and International Energy Policy Office of Environmental Analysis, Office of Health and Environmental Research, Environmental Sciences Div.
(Contract W-7405-eng-48)
(DE95-006430; UCRL-ID-119123) Avail: CASI HC A03/MF A01

As part of the intercomparison of radiation codes in climate models (ICRCCM) process of comparing radiative transfer parameterizations used in climate models, several data sets were made available to the radiative modeling community. While a comprehensive report will be issued following a meeting of all participating groups, this report documents the LLNL input to this study. Calculations of the downward infrared (IR) surface radiances have been made in the 500-3,000 cm(exp -1) wavenumber range in accordance with the set of ICRCCM test cases provided to all interested modeling groups. The atmospheric test cases were obtained from clear sky observations of the temperature, pressure, and major trace gas distributions at altitudes from the surface to about 30 km. A set of high resolution observations of the downward radiances, plus a set of line by line radiance calculations in the 500-3,000 cm(exp -1) wavenumber range, for each of the test cases was also supplied. Comparison of the Lawrence Livermore National Laboratory (LLNL) theoretical calculations of the integrated radiances over 25 cm(exp -1) subintervals with the observations and the line by line results shows good agreement over most of the wavenumber range. MEASUREMENT OF HETEROGENEOUS CHEMICAL PROCESSES RELEVANT TO AEROSOL SURFACES AND TRACE GASES ACTIVE IN THE MARINE ENVIRONMENT Progress Report, Feb. 1994 - Jan. 1995

P. Davidovits, D. R. Worsnop (Aerodyne Research, Inc., Billerica, MA.), M. S. Zahniser (Aerodyne Research, Inc., Billerica, MA.), J. T. Jayne (Aerodyne Research, Inc., Billerica, MA.), and C. E. Kolb (Aerodyne Research, Inc., Billerica, MA.) Feb. 1995 19 p
(Contract DE-FG02-91ER-61208)
(DE95-008337; DOE/ER-61208/4) Avail: CASI HC A03/MF A01

Biogenically produced reduced sulfur compounds from the marine environment, deliver a sulfur burden to the atmosphere which is about half as large as that due to sulfur oxides produced by fossil fuel combustion. The multiphase chemical processes for these species must be understood in order to evaluate the relative roles of biogenic and combustion produced sulfur oxides over the oceans. The aim of the studies funded by the subject DOE grant is to measure parameters governing the heterogeneous chemistry of the species occurring in the marine environment. During the past year, uptake studies for the sulfur species MSA, DMSO, DMSO2, DMS, OCS, CS2, H2S, and CH3SH have been finalized. Studies of the reactive uptake of Cl2 and Br2 by Br(-) and I(-) solutions as a function of temperature have been completed. The uptake of O3 by aqueous NaI solutions has also been studied for the purpose of comparison. We have begun co-deposition studies and have obtained some preliminary results for the codeposition with ozone of DMS, DMSO, DMSO2 and MSA. For the next phase of the work, a new horizontal bubbler apparatus was designed and built and construction to improve the detection sensitivity of the apparatuses was begun. Altogether during 1994, 8 articles have been accepted for publication and 2 Ph.D. dissertations have been submitted and approved. DOE

MULTIMEDIA ENVIRONMENTAL POLLUTANT ASSESSMENT SYSTEM (MEPAS) APPLICATION GUIDANCE. GUIDELINES FOR EVALUATING MEPAS INPUT PARAMETERS FOR VERSION 3.1

J. W. Buck, G. Whelan, J. G. Droppo, Jr., D. L. Strenge, K. J. Castleton, J. P. McDonald, C. Sato, and G. P. Streile Feb. 1995 205 p

(Contract DE-AC06-76RL-01830)
(DE95-007525; PNL-10395) Avail: CASI HC A10/MF A03

The Multimedia Environmental Pollutant Assessment System (MEPAS) was developed by Pacific Northwest Laboratory (PNL) for the U.S. Department of Energy (DOE) Office of Environment, Safety and Health and Office of Environmental Management and Environmental Restoration. MEPAS is a set of computer codes developed to provide decision makers with risk information integrated for hazardous, radioactive, and mixed-waste sites based on their potential hazard to public health. It is applicable to a wide range of environmental management and regulatory conditions, including inactive sites covered under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) and active air and water releases covered under the Clean Air Act, the Clean Water Act, and the Resource Conservation and Recovery Act. MEPAS integrates contaminant release, transport, and exposure models into a single system. An interactive user interface assists the investigator in defining problems, assembling data and entering input, and developing reports. PNL has compiled two documents that explain the methodology behind the MEPAS model and instruct the user in how to input, retrieve, and evaluate data. This report contains detailed guidelines for defining the input data required to conduct an analysis with MEPAS. Entries for each variable have a short definition, units, and text explaining what a variable is and how it can be quantified. As appropriate, ranges and typical values are given. This report also contains listings of the input screens (worksheets) that are used in the MEPAS user interface for these variables. DOE

A STUDY OF SURFACE TEMPERATURES, CLOUDS AND NET RADIATION Semiannual Report
Harbans Dhuria 1 Mar. 1994 29 p
(Grant NAG5-2345)
(NASA-CR-198589; NAS 1.26:198589) Avail: CASI HC A03/MF A01

The study is continuing and it is focused on examining seasonal relationships between climate parameters such as the surface temperatures, the net radiation and cloud types and amount on a global basis for the period February 1985 to January 1987. The study consists of an analysis of the combined Earth Radiation Budget Experiment (ERBE) and International Satellite Cloud Climatology Program (ISCCP) products. The main emphasis is on obtaining the information about the interactions and relationships of Earth Radiation Budget parameters, cloud and temperature information. The purpose is to gain additional qualitative and quantitative insight into the cloud climate relationship. Author

EVALUATION AND QUALIFICATION OF ENVIRONMENTALLY CONSCIOUS MANUFACTURING PROCESSES FOR COMMERCIAL AND MILITARY APPLICATIONS
D. J. Anderson, R. M. Cranwell, R. Iman, and P. D. VanBuren 1995 5 p Presented at the IEEE International Symposium on Electronics and the Environment, Orlando, FL, 1-3 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008520; SAND-95-0315C; CONF-950591-1) Avail: CASI HC A01/MF A01

Environmental regulations are encouraging the development of new environmentally conscious manufacturing (ECNP) processes. However, the quality and reliability of these processes and hardware produced must be understood prior to implementing these new technologies in factories. Furthermore, military hardware fabrication is governed by standards and specifications that frequently mandate the use of older, less environmentally friendly processes or materials, or prohibit the use of new ECM processes without advance military approval. Sandia National Laboratories, with industrial and military partners, have developed methodologies for evaluating and qualifying new ECM processes for military and commercial applications, and have piloted these methodologies in qualifying new, low-residue soldering technologies and materials. INVESTIGATION ON COMPREHENSIVE FOSSIL FUEL CYCLE ANALYSIS AND ASSESSMENT APPROACH AS VIEWED FROM THE GLOBAL ENVIRONMENT
Mar. 1994 280 p In JAPANESE
(DE95-759241; NEDO-P-9330) Avail: CASI HC A13/MF A03

Investigations are conducted with the aim of establishing the comprehensive fuel cycle analysis and assessment method for the power generation cycle which is provided with CO2 recovery and treatment facilities. Power plants (600MW each) of oxygen-blown IGCC and LNG GTCC are chosen for the model study. A base case where the power plant has no CO2 recovery facilities and a case where it has them are studied for each plant. As CO2 recovery technology, the physical absorption/SELEXOL method is adopted to IGCC and the chemical absorption/MEA method to GTCC. Methods to process the recovered CO2 are deep sea water injection, making it clathrate/injection into the sea bottom, and injection into the underground and the oil well. The energy output is approximately 1.03-1.96 times larger in IGCC than in the base case, and approximately 1.02-1.39 times larger in GTCC. The energy balance is calculated by a ratio of sending-end output to energy output. The energy balance in CO2 recovery is approximately 7.7-3.9 and 6.2-4.6 in IGCC and GTCC, respectively, with decreases of about 24-61% in IGCC and 16-38% in GTCC. DOE

INVESTIGATION ON WORKING OUT THE GLOBAL REGENERATION PLAN
Mar. 1994 139 p In JAPANESE
(DE95-759246; NEDO-GET-9309) Avail: CASI HC A07/MF A02

Measures to reduce the CO2 emission which mainly causes the global warming were tabulated for their technological evaluation with objective indexes. The measures were evaluated in technology, economy and subsidiary influence at four stage levels, which were the theoretical level, experimental level based on the present technology, demonstration level and future level to presume the future technological progress. The evaluation was itemized into CO2 production rate, energy efficiency and net reducible quantity of CO2. Those items were related to the problem extraction of technological development. In the subsidiary influence evaluation, the technology in question is assessed in its influence on the global environment and ecological system when it is widely propagated. In the economic evaluation, the investment initial cost and operation running cost are separately and clearly studied for the introduction of technology. Though test application was made to the fuel conversion, energy saving manufacturing and CO2 fixation, the investigation to establish the quantitative and reliable evaluation is left as a future problem. SURVEY ON RESEARCHES RELATED TO OCEAN DISPOSAL OF CARBON DIOXIDE
Mar. 1994 147 p In JAPANESE
(DE95-759247; NEDO-GET-9307) Avail: CASI HC A07/MF A02

Pertaining to the CO2 ocean disposal, surveys were made on the equilibrium and transport properties of CO2-water system, mass transfer models of CO2 in the ocean, behavior of deepsea organisms and ecosystem, economical efficiency of CO2 ocean storage, and overseas technical trend of CO2 ocean disposal. For the equilibrium properties, the data with CO2 hydrate are not sufficiently obtainable with very few examples particularly of measuring the diffusivity at high pressures, so that the conventional methods of estimation can possibly not be applied. For the mass transfer models, the simulation is still at a basic stage. For the deepsea organisms, it is necessary to research into the adaptability and adaption speed of ecosystem to the change in pH due to CO2, vertical food chains between the sea surface and bottom, and oceanic ecosystem simulation model on the global level. To evaluate the economical efficiency of CO2 ocean storage, it was known that, though properly applicable in Japan, the liquid CO2 deepsea storage is still difficult in economy. DOE

N95-27941# New Energy and Industrial Technology Development Organization, Tokyo (Japan).
INVESTIGATION ON TECHNOLOGY FOR INCREASING THE BIOLOGICAL CO2 SINK AND TECHNOLOGY FOR CO2 FIXATION AND REUTILIZATION
Mar. 1994 227 p In JAPANESE
(DE95-759251; NEDO-GET-9301) Avail: CASI HC A11/MF A03

An investigational study is conducted on chemical measures to reduce

CO2 environmental loads. For artificial increasing of the CO2 sink, desert planting and afforestation are important. Besides, anticipated are utilization of solar energy and application of biotechnology such as genetic manipulation. Prevention of deforestation is also important. CO2 fixation in the weathering process of silicate rocks is worth studying. There is a method in which phytoplankton is increased by applying fertilizer into the surface layer of the ocean to promote CO2 absorption/fixation into the ocean. CO2 absorption reactors using microalgae are also proposed. For CO2 fixation and reutilization, the paper studies a photochemical/electrochemical method in which the solar cell power generation and chemical reaction are directly combined, and a photocatalytic method. In the former method, the solar cell power generation is combined with water electrolysis or electrolytic reduction of CO2. In the latter, hydrogen is directly produced and CO2 reduction product is obtained. Also investigated is CO2 fixation/reutilization using various kinds of synthesis by CO2, hydrogen and organic matters. DOE

N95-27942# New Energy and Industrial Technology Development Organization, Tokyo (Japan).
INVESTIGATION ON LCA (LIFE CYCLE ANALYSIS/ASSESSMENT)
Mar. 1994 141 p In JAPANESE
(DE95-759260; NEDO-GET-9304) Avail: CASI HC A07/MF A02

Importance is attached to the life cycle analysis/assessment (LCA) which is a method to analyze and assess the load of products on the environment for the enterprises to concretely take environment protecting actions. To initiate the LCA research, a survey was conducted which covered the collection of information, at home and abroad, about the LCA R and D, development of LCA quantification, and case study related to the power generation/distribution, steel making and chemical process. For the selective assessment of element materials, the LCA was developed mainly around the chemical process, and its framework structured by the EPA and SETAC is worldwidely recognized to be basically used. That framework is composed of target setting and general aspect, inventory analysis, influence assessment, and improvement assessment. As an example of research, surveyed was the present status of the above four items of framework. In case of survey by international organizations, it is absolutely necessary that the data to be compared are identical in quality and definition. Conditions to apply the LCA and problems were also pointed out. DOE

(DE95-006441; UCRL-JC-118555; CONF-9406301-1) Avail: CASI HC A03/MF A01

Our belief that climate will inexorably change is driven by the very clear evidence of chemical abundance changes in the atmosphere during the last four decades. In the past, this belief has led to the development of two separate efforts: to understand and build models describing the physical climate system and to understand and build models of the chemical climate system. But how will these two systems interact? Are there important chemical changes that result from climate change that need to be understood and properly accounted for in order to predict the evolution of the climate system? Are there important climate changes that may affect chemical abundances that must be addressed? Large strides have been made in our capability to predict both the physical climate system and the chemical climate system during the past few years. In spite of extant uncertainties in both general circulation models (GCM's) and chemical transport models (CTM's), we should begin the process of understanding how and to what extent these errors might propagate in the coupled system. We have outlined a strategy for quantifying the effective uncertainties and have defined a few initial steps in the process. Systematic study of the importance of uncertainties and their impact in the coupled system is a prerequisite to progress in coupling the chemical and climate systems. Such coupling is necessary if we are to predict the evolution of climate in the future. DOE

RESEARCH PROJECT ON CO2-INDUCED CLIMATE CHANGE Annual Progress Report, 1 Mar. 1994 - 28 Feb. 1995
R. D. Cess and S. Hameed 1995 8 p
(Contract DE-FG02-85ER-60314)
(DE95-008339; DOE/ER-60314/6) Avail: CASI HC A02/MF A01

This summarizes current progress in the research project at SUNY Stony Brook on CO2-induced climate change. Three tasks are described, corresponding to the task categories in the US DOE/PRC CAS cooperative project on climate change. Task 1 concerns the intercomparison of CO2 related climatic warming in contemporary general circulation models. Task 2 looks at understanding the natural variability in climatic data and comparing its significant features between observations and model simulations. Task 3 focuses on analysis of historical climate data developed at the Institute of Geography of the Chinese Academy of Sciences. DOE

CARBONACEOUS AEROSOLS INFLUENCING ATMOSPHERIC RADIATION: BLACK AND ORGANIC CARBON
J. E. Penner Sep. 1994 35 p Presented at the Dahlem Workshop, Berlin, Germany, 24 Apr. 1994
(Contract W-7405-eng-48)
(DE95-006437; UCRL-JC-118866; CONF-9404123-2) Avail: CASI HC A03/MF A01

Carbonaceous particles in the atmosphere may both scatter and absorb solar radiation. The fraction associated with the absorbing component is generally referred to as black carbon (BC) and is mainly produced from incomplete combustion processes. The fraction associated with condensed organic compounds is generally referred to as organic carbon (OC) or organic matter and is mainly scattering. Absorption of solar radiation by carbonaceous aerosols may heat the atmosphere, thereby altering the vertical temperature profile, while scattering of solar radiation may lead to a net cooling of the atmosphere/ocean system. Carbonaceous aerosols may also enhance the concentrations of cloud condensation nuclei. This paper summarizes observed concentrations of aerosols in remote continental and marine locations and provides estimates for the fine particle (D less than 2.5 microns) source rates of both OC and BC. The source rates for anthropogenic organic aerosols may be as large as the source rates for anthropogenic sulfate aerosols, suggesting a similar magnitude of direct forcing of climate. The role of BC in decreasing the amount of reflected solar radiation by OC and sulfates is discussed. The total estimated forcing depends on the source estimates for organic and black carbon aerosols which are highly uncertain. The role of organic aerosols acting as cloud condensation nuclei (CCN) is also described. DOE

APPLICATION OF MODERN DIAGNOSTIC METHODS TO ENVIRONMENTAL IMPROVEMENT Annual Progress Report, Jan. - Oct. 1994
W. S. Shepard Dec. 1994 193 p
(Contract DE-FG02-93CH-10575)
(DE95-005797; DOE/CH-10575/T2) Avail: CASI HC A09/MF A03

The Diagnostic Instrumentation and Analysis Laboratory (DIAL), a research department in the College of Engineering at Mississippi State University (MSU), is under contract with the US Department of Energy (DOE) to develop and apply advanced diagnostic instrumentation and analysis techniques to real world processes; measurements are made in hot, highly corrosive atmospheres in which conventional measurement devices are ineffective. Task 1 of this agreement is concerned with the development and application of various diagnostic methods to characterize the plasma properties, the melt properties and the downstream emissions from a plasma torch facility designed to vitrify mixed waste. Correlation of the measured properties with the operating parameters of the torch will be sought to improve, optimize and control the overall operation of the plasma treatment process. As part of this program, diagnostic methods will be developed and evaluated for characterization, monitoring and control purposes of treatment processes in general. Task 2 of this agreement is concerned with the development of a system to monitor and control the combustion stoichiometry in real time in order to minimize environmental impact and maximize process efficiency. Staged fuel injection is also being studied to minimize NO(x) formation. DOE

ANOMALOUS CLOUD ABSORPTION? A CRITIQUE OF THE PAPER ENTITLED ABSORPTION OF SOLAR RADIATION BY CLOUDS: OBSERVATIONS VERSUS MODELS
D. G. Imre and E. Abramson Feb. 1995 33 p
(Contract DE-AC02-76CH-00016)
(DE95-007703; BNL-61427) Avail: CASI HC A03/MF A01

In a recent paper R. Cess and co-authors attempt to prove that general-circulation-models of the atmosphere do not correctly calculate short-wave absorption by cloudy sides. Co-located satellite and surface measurements are used to assess the relative effects of clouds on short-wave fluxes at both the top of the atmosphere and at the surface. The differences, expressed as average, Cloud-Radiative-Forcing (CRF) ratios, am evaluated both directly from measured fluxes and indirectly from plots of the Top-Of-Atmosphere (TOA) albedo against transmission. The two different analyses are then connected via their equation 1. Our study of the paper raised the serious concern that, due to unexamined uncertainties in their analyses, their final conclusions are not well founded. Herein, we give critiques of their two basic methods of analysis, referred to as 'the slope' and 'the direct CRF' methods. DOE

FY 1994 AMBIENT AIR MONITORING REPORT FOR MCMURDO STATION, ANTARCTICA
R. M. Lugar Dec. 1994 69 p
(Contract DE-AC07-94ID-13223)
(DE95-008565; INEL-94/0114) Avail: CASI HC A04/MF A01

This report presents the results of ambient air monitoring performed during the 1994 fiscal year (FY 1994) in the vicinity of McMurdo Station, Antarctica. Routine monitoring was performed during the 1993-1994 austral summer at three locations for airborne particulate matter less than 10 micrometers (PM-10) and at two locations for carbon monoxide (CO), sulfur dioxide (SO2), and nitrogen oxides (NO, (NO2), and (NO(x)). Selected PM-10 filters were analyzed for arsenic, beryllium, cadmium, chromium, lead, mercury, and nickel. Additional air samples were collected at three McMurdo area locations and at Black Island for determination of the airborne concentration of polychlorinated dibenzo-p-dioxins (PCDD's) and polychlorinated dibenzofurans (PCDF's). Sampling site selection, sampling procedures, and quality assurance procedures used were consistent with US Environmental Protection Agency guidance for local ambient air quality networks. DOE

TOWARDS THE DETECTION AND ATTRIBUTION OF AN ANTHROPOGENIC EFFECT ON CLIMATE
B. D. Santer, K. E. Taylor, J. E. Penner, T. M. L. Wigley, and P. D. Jones Jan. 1995 84 p
(Contract W-7405-eng-48)
(DE95-008589; UCRL-ID-119098; PCMDI-21) Avail: CASI HC A05/MF A01

It has been hypothesized recently that cooling caused by anthropogenic sulfate aerosols may be obscuring a warming signal associated with changes in greenhouse gas concentrations. Here the authors use results from model experiments in which sulfate and carbon dioxide have been varied individually and in combination in order to determine whether the simulated surface temperature change patterns are increasingly evident in observed records of temperature change. They use centered (R(t)) and uncentered (C(t)) pattern correlation statistics in order to compare observed time-evolving surface temperature change patterns with the model-predicted equilibrium signal patterns. They show that in the case of temperature signals from the 'CO2-only' and 'sulfate-only' experiments, the C(t) statistic essentially reduces to a measure of observed global-mean temperature changes, and cannot be used to uniquely attribute observed climate changes to a specific causal mechanism. For the signal from the experiment with combined CO2/sulfate aerosol forcing, C(t) provides information on pattern congruence, but trends in C(t) are difficult to interpret without decomposing the statistic into pattern similarity and global-mean change components. They therefore focus on R(t), which is a more useful statistic for discriminating between forcing mechanisms with different pattern signatures but similar rates of global mean change. DOE

SIHTI 2: ENERGY AND ENVIRONMENTAL TECHNOLOGY. YEARBOOK 1993 OF THE RESEARCH PROGRAMME
M. Korhonen, ed. and K. Saviharju, ed. 1994 250 p
(DE95-755135; VTT-SYMP-144) Avail: CASI HC A11/MF A03

The SIHTI 2 research programme on energy and environmental technology, established by the Finnish Ministry of Trade and Industry, is concentrating on areas of environmental technology that are vital to Finland or in which Finns can engage in pioneering research. The promotion of product development within the environmental technology industry produces solutions for reducing the emissions of the energy sector. It is also a way of boosting Finland's share of the world market for such technology. The objectives of the programme are to cut down harmful emissions, recycle raw materials, reduce the amount of byproducts and wastes and achieve a greater utilization of wastes. In addition, an objective is to create basic information about the effects of environmental protection technology for the other research programmes financed by the Ministry of Trade and Industry. The development of internationally comparable research, monitoring and measurement methods creates a basis for wide-ranging international cooperation. The programme, to be carried out in 1993 - 1998, is in part a continuation of the previous SIHTI programme. New areas of research are environmental problems connected with energy in the forest and base metal industries as well as the systematic development of life-cycle analyses. This publication is yearbook 1993 of the programme. It contains the project reports of the research and joint development projects and information about the participating institutions. DOE

SURVEY ON BIO-CHEMICAL COMPLEX HARMONIZED WITH GLOBAL ENVIRONMENT
Mar. 1994 258 p
(DE95-759252; NEDO-GET-9303) Avail: CASI HC A12/MF A03

In order to develop the process and product harmonized with the global environment, a bio-chemical complex was structured which was focused on the biological technology. The substitution of biological technology for the conventional system of a large energy consumption type was engineered to be maximized by using the unutilized biomass as recyclable resources. A field survey was made and reported on the actual state of biomass resources, agriculture and forestry in the Philippines and Thailand. Then, mention was made of their problems of effective utilization. As a biological technology, selected were the hydrogen production, methane fermentation, CO2 fixation, biodegradation plastics and synthesized single cell protein. As a bioreactive or other selective refining technology, study was made of the film, chromatography, solvent extraction, adsorption, electrophoresis, distillation and crystallization. Besides the concentration as a petrochemical complex, it is also effective to take the local properties into consideration and distribute the production bases on a worldwide scale. DOE

EVALUATION OF MICROPOROUS CARBON FILTERS AS CATALYSTS FOR OZONE DECOMPOSITION
L. Whinnery, D. Coutts, C. Shen, R. Adams, C. Quintana (Sandia National Labs., Albuquerque, NM.), and S. Showalter (Sandia National Labs., Albuquerque, NM.) 1994 7 p Presented at the 1994 Fall Meeting of

the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-006498; SAND-95-8451C; CONF-941144-73) Avail: CASI HC A02/MF A01

Ozone is produced in small quantities in photocopiers and laser printers in the workplace and large quantities in industrial waste water treatment facilities. Carbon filters are commonly used to decompose this unwanted ozone. The three most important factors in producing a filter for this purpose are flow properties, efficiency, and cost. Most ozone decomposition applications require very low back-pressure at modest flow rates. The tradeoff between the number of pores and the size of the pores will be discussed. Typical unfiltered emissions in the workplace are approximately 1 ppm. The maximum permissible exposure limit, PEL, for worker exposure to ozone is 0.1 ppm over 8 hours. Several methods have been examined to increase the efficiency of ozone decomposition. Carbon surfaces were modified with catalysts, the surface activated, and the surface area was increased, in attempts to decompose ozone more effectively. Methods to reduce both the processing and raw material costs were investigated. Several sources of microporous carbon were investigated as ozone decomposition catalysts. Cheaper processing routes including macropore templating, faster drying and extracting methods were also studied. DOE

THE NORTHERN WINTERTIME DIVERGENCE EXTREMA AT 200 hPa AND SURFACE CYCLONES AS SIMULATED IN THE INTEGRATION OF THE ECMWF GENERAL CIRCULATION MODEL

J. S. Boyle Nov. 1994 30 p
(Contract W-7405-eng-48)
(DE95-007946; UCRL-ID-114037) Avail: CASI HC A03/MF A01

Divergence and convergence centers at 200 hPa and mean sea level pressure (MSLP) cyclones were located every 6 hr for a 10-yr general circulation model (GCM) simulation with the ECMWF (Cycle 36) for the boreal winters from 1980 to 1988. The simulation used the observed monthly mean sea surface temperature (SST) for the decade. Analysis of the frequency, location, and strength of these centers and cyclones gives insight into the dynamical response of the model to the varying SST. The results indicate that: (1) the model produces reasonable climatologies of upper-level divergence and MSLP cyclones; (2) the model distribution of anomalies of divergence and convergence centers and MSLP cyclones is consistent with observations for the 1982-83 and 1986-87 El Nifio events; (3) the tropical Indian Ocean is the region of greatest divergence activity and interannual variability in the model; (4) the variability of the divergence centers is greater than that of the convergence centers; (5) strong divergence centers occur chiefly over the ocean in the midlatitudes but are more land-based in the tropics, except in the Indian Ocean; and (6) locations of divergence and convergence centers can be a useful tool for the intercomparison of global atmospheric simulations. DOE

A COMPARISON OF NH3 POINT MONITORING AND DIODE LASER BASED PATH INTEGRATED MEASUREMENTS

N. Goldstein, S. C. Richtsmeier, J. Lee, F. Bien, G. J. Fetzer (Monitor Labs, Inc., Englewood, CO.), and K. W. Groff (Monitor Labs, Inc., Englewood, CO.) 1994 17 p Presented at the Optical Sensing for Environmental and Process Monitoring, McLean, VA, 7-10 Nov. 1994
(Contract DE-FG02-91ER-81196)
(DE95-006892; CONF-9411144-4) Avail: CASI HC A03/MF A01

Measurements made using two different types of ammonia monitors during a two-month field study in the summer of 1994 are discussed. The first was a diode-laser based open path monitor designed for automated operation in an industrial environment. The second is a monitoring analyzer based on thermal decomposition of ammonia to NO and subsequent analysis by O3 - NO chemiluminescence. The two monitors provided consistent measurements of ammonia concentration during weeks of continuous unattended operation. DOE

THE GLOBAL HISTORICAL CLIMATOLOGY NETWORK: A PREVIEW OF VERSION 2

R. S. Vose, R. L. Schmoyer, T. C. Peterson, and J. K. Eischeid 1995 6 p Presented at the 75th Annual Meeting of the American Meteorological Society: Diamond Anniversary, Dallas, TX, 15-20 Jan. 1995
(Contract DE-AC05-84OR-21400)
(DE95-007003; CONF-950124-6) Avail: CASI HC A02/MF A01

Instruments that could reliably measure temperature, precipitation, and pressure were developed by the late 17th and early 18th centuries. It has been estimated that weather records have been collected at one to two hundred thousand locations since those first instruments were placed in the field. Numerous applications, from global change studies to climate impact assessments to general circulation models, make use of such historical records. Given their importance, it is unfortunate that one cannot approach a single researcher or data center to acquire all of the records for all of the stations, or even a large portion of them. In 1990, the Carbon Dioxide Information Analysis Center (CDIAC), the National Climatic Data Center (NCDC), and the World Meteorological Organization (WMO) undertook a collaborative effort aimed at solving this problem. The initiative completed its first data product, known as the Global Historical Climatology Network (GHCN) version 1.0, in 1992. This data base contains quality-controlled monthly climatic time series from 6,039 temperature, 7,533 precipitation, 1,883 sea level pressure, and 1,873 station pressure stations located on global land areas. This paper describes the data and methods being used to compile GHCN version 2.0, an expanded and improved version of its predecessor. Planned for distribution in early 1995, its enhancements will include: (1) data for additional stations--perhaps three times as many as in version 1.0, plus maximum/minimum temperature measurements; (2) detailed assessments of data quality, including nearest-neighbor checks; and (3) adjustments for nonclimatic inhomogeneities, such as station relocations and land use changes. STRATOSPHERIC OZONE REACTIVE CHEMICALS GENERATED BY SPACE LAUNCHES WORLDWIDE

B. B. Brady, E. W. Fournier, L. R. Martin, and R. B. Cohen 1 Nov. 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F04710-88-C-0089)
(AD-A289852; TR-94(4231)-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We report quantities of inorganic chlorine compounds and aluminum oxide particles (Al2O3) deposited in the stratosphere and troposphere by solid rocket propelled launch vehicles. Totals are presented by launch vehicle type, summarized on an annual basis, and projected to the year 2010 using standard mission models. Data are given for Air Force, NASA (shuttle and expendable vehicles), the European Space Agency (ESA) (Ariane 5), and the Japanese Space Agency (H-1 and H-2). Whereas inorganic chlorine compounds released by solid rockets are directly related to stratospheric ozone depletion, much uncertainty surrounds reactivity of aluminum oxide particles. We also compare current and future effects of space launch on stratospheric ozone depletion with those of Ozone Depleting Chemicals (ODC's). As a baseline, we use projections of future ODC use by SMC, Air Force Materiel Command (AFMC), and the world. Relevant stratospheric chemistry is considered to make a legitimate comparison of ODC and solid rocket exhaust. DTIC

A BLACK CARBON EMISSION DATA BASE FOR ATMOSPHERIC CHEMISTRY AND CLIMATE STUDIES

J. Dignon, H. E. Eddleman, and J. E. Penner Oct. 1994 3 p
(Contract W-7405-eng-48)
(DE95-006436; UCRL-ID-119104) Avail: CASI HC A01/MF A01

A global data base of black carbon emissions to the atmosphere from fossil fuel combustion has been compiled for the use in atmospheric chemistry and climate studies. The resolution provided is at 1(degree) latitude by 1(degree) longitude based on previous work by Matthews, Lemer et al., and Dignon. A more extensive description of the assumptions made and emission factors used in this data base can be found in Penner et al. The original work of Penner et al. provides the emissions inventory data on a 5(degree) by 5(degree) resolution. The units of emission for this updated version of the inventory yield a global total of 12.6 TgC/y and are given as the mass in metric tons of carbon for each 1(degree) x 1(degree) grid. It is important to note that this is not equivalent to a flux, in that the area of the grid boxes vary latitudinally. The emissions are expected to represent the emissions for a typical mid-1980s year. The distribution of emission is based on national totals and then mapped on to the 1(degree) x 1(degree) grid according to the updated population mapping of Logan. A description of this mapping procedure can be found in Dignon. DOE

Avail: CASI HC A10/MF A03

The Data Assimilation Office (DAO) at Goddard Space Flight Center has produced a multiyear global assimilated data set with version 1 of the Goddard Earth Observing System Data Assimilation System (GEOS-1 DAS). One of the main goals of this project, in addition to benchmarking the GEOS-1 system, was to produce a research quality data set suitable for the study of short-term climate variability. The output, which is global and gridded, includes all prognostic fields and a large number of diagnostic quantities such as precipitation, latent heating, and surface fluxes. Output is provided four times daily with selected quantities available eight times per day. Information about the observations input to the GEOS-1 DAS is provided in terms of maps of spatial coverage, bar graphs of data counts, and tables of all time periods with significant data gaps. The purpose of this document is to serve as a users' guide to NASA's first multiyear assimilated data set and to provide an early look at the quality of the output. Documentation is provided on all the data archives, including sample read programs and methods of data access. Extensive comparisons are made with the corresponding operational European Center for Medium-Range Weather Forecasts analyses, as well as various in situ and satellite observations. This document is also intended to alert users of the data about potential limitations of assimilated data, in general, and the GEOS-1 data, in particular. Results are presented for the period March 1985-February 1990. Author

FTIR MEASUREMENTS OF THERMAL INFRARED SKY RADIANCE AND TRANSMISSION
C. L. Bennett Jul. 1994 13 p Presented at the Annual Meeting of the Society of Photo-Optical Instrumentation Engineers, San Diego, CA, 24-29 Jul. 1994
(Contract W-7405-eng-48)
(DE95-003642; UCRL-JC-117864; CONF-940723-33) Avail: CASI HC A03/MF A01

Precise relative measurements of sky continuum and line emission and absorption have been made using Fourier transform infrared (FTIR) spectroscopy. During conditions of horizontally uniform air composition, measurements of the variation of the spectral radiance with elevation angle sample an air column that varies simply as the cosecant of the elevation angle. In spectral regions that are optically thin, an extrapolation to zero air mass can be used to accurately determine instrumental background. An ambient temperature black body reference furnishes an accurate measurement of the instrumental spectral response. The excess sky emission above instrumental background relative to the local black body reference spectrum thus provides a calibrated sky radiance spectrum. This spectrum can be used to calculate the atmospheric transmission. As a test, transmission spectra have been directly obtained with the full moon as a backlighting source, and are in excellent agreement with the sky radiance derived transmission spectra. For spectral regions dominated by water, the continuum emission has been measured for paths involving the entire atmospheric column. Reasonable agreement with previous laboratory measurement of the continuum strength is obtained. DOE

A STUDY OF MAGNETIC ACTIVITY EFFECTS ON THE THERMOSPHERIC WINDS IN THE LOW IONOSPHERE M.S. Thesis - Utah State Univ.
Ricardo Cruz Davila Sep. 1994 196 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288677; AFIT/CI/CIA/94-138) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purpose of this thesis is to examine the effects of magnetic activity on the low latitude F-region thermospheric winds. The F-region (120-1600 km) is a partially ionized medium where O+ and O are the major ion and neutral species, respectively. The thermospheric winds at these altitudes are driven primarily by pressure gradient forces resulting from the solar heating during the day and cooling at night. For this study, we use measured Fabry-Perot Interferometer (FPI) winds at Arequipa (16.5 deg S, 71.5 deg W) and measured FPI and incoherent Scatter Radar (ISR) winds at Arecibo (18.6 deg N, 66.8 deg W). AN IMPROVED MODEL OF HIGH-LATITUDE F-REGION SCINTILLATION (WBMOD VERSION 13) Final Report, 1 Sep. 1993 - 31 Aug. 1994
James A. Secan and Robert M. Bussey 31 Aug. 1994 93 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-91-C-0152)
(AD-A288558; NWRA-CR-94-R120; PL-TR-94-2254) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Many modern military systems used for communications, command and control, navigation, and surveillance depend on reliable and relatively noise-free transmission of radiowave signals through the earth's ionosphere. Small-scale irregularities in the ionospheric density can cause severe distortion, known as radiowave scintillation, of both the amplitude and phase of these signals. The WBMOD computer program can he used to estimate these effects on a wide range of systems. The objective of this study is to investigate improvements to the WBMOD model based on extensive data sets covering both the equatorial and high-latitude regimes. This report summarizes the work completed during the third year of this project, which includes completion of the new model for the high-latitude (auroral and polar cap) region of the WBMOD model. A PROBABILISTIC TARGET CLASSIFICATION AND DESCRIPTION MODEL FOR SEISMIC SENSORS M.S. Thesis
Mark David vanKan Sep. 1994 104 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288548) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Unattended ground sensors have a tremendous potential for providing information about battlefield targets, but for the most part this potential has been unrealized. The Marine Corps has recently fielded the Phase V seismic sensors of the Tactical Remote Sensor System (TRSS). These sensors are more sensitive than any of the previous versions, and their potential to provide more detailed target information is also greater than that of previous sensors. The current target classification and description model used by TRSS was developed for sensors which were placed in use in the early 1960's. The model is simple and deterministic in nature, and does not take into account the variance in the sensor system or the variance in sensor performance due to target type, target velocity, soil composition, or other potential factors. This thesis examines the sensor system variance and the effect of target type on sensor performance through field testing and develops an improved model for target description that accounts for these effects. The revised model takes advantage of the measured sensor characteristics to better describe the target, and provides the user with bounds that describe the credibility of the model's estimate. DTIC

MESO-BETA SCALE NUMERICAL SIMULATION STUDIES OF TERRAIN-INDUCED JET STREAK MASS/MOMENTUM PERTURBATIONS Final Report
Yuh-Lang Lin and Michael L. Kaplan May 1995 177 p Sponsored by NASA Headquarters
(Grant NAG5-1790)
(NASA-CR-197804; NAS 1.26:197804) Avail: CASI HC A09/MF A02

Mesoscale model simulations provide insight into the complex jet streak adjustments on 11-12 July 1981 that preceded the first of two significant gravity wave events to have been generated over the Rocky Mountains in Montana. Simulations employing a variety of terrain treatments indicate that prior to wave formation, geostrophic adjustment processes modified the structure of the mid-upper tropospheric jet streak by creating secondary jetlets to the southeast of the polar jet streak in proximity to the gravity wave generation region. This simulated restructuring of the mid-upper tropospheric jet streak is the result of a four stage process. During stage 1, the wind adjusts to the mass field as the jet streak exit region propagates into the inflection point between the upstream trough and downstream ridge in the height field. Stage 2 is initiated as the mass field is forced to adjust to the new ageostrophic wind field created during stage 1. Stage 3 is defined by a second geostrophic adjustment process occurring in a similar manner but to the south and east of the adjustment which occurs during stage 1. A low-level mesoscale jetlet is formed during stage 4 in response to the low-level pressure falls that are established during stage 3. The perturbation of this jetlet, caused by orographically-induced adiabatic and diabatic physical processes, is the likely mechanism responsible for the generation of the first and second episode of observed gravity waves. The dynamics responsible for this wave episode are discussed as differential surface sensible heating inducing an orographically-forced mountain-plains solenoid, resulting in the formation of additional mesoscale jetlets and internal gravity waves. Also discussed is how convective latent heating modifies the numerically simulated terrain-induced internal gravity waves, especially their amplitude and phase velocities, which provide better agreement with those wave characteristics observed in nature. Finally, the three-dimensional linear response of a zonally uniform barotropic flow in a vertically unbounded, continuously stratified, Boussinesq atmosphere which is perturbed from geostrophic equilibrium is investigated.

(NASA-CR-197737; NONP-NASA-VT-95-42904) Avail: CASI VHS A02/BETA A22

In this first part of a four part 'Passport to Knowledge Special', hosted by Camille Jennings from Maryland Public Television, children from Maryland and Texas schools had the opportunity to directly interact with and ask questions of scientists and researchers in Antarctica live. The physical characteristics of Antarctica are featured, along with their effects on the human and microbiological organisms living in the region. The reasons behind the clothing worn in the Antarctic and the importance of the meteorological station are featured. Interviews with Professor Ian Dolziel (U of Texas) and Lt. commander John Joseph, NSFA (the head of the Navy Meteorology Center) occur with the school children, along with actual video footage of the surrounding geological features and geography. The 'Weatherops' is located at McMurdo Station, Antarctica. CASI

A PARALLEL COUPLED OCEANIC-ATMOSPHERIC GENERAL CIRCULATION MODEL
Michael F. Wehner, Al J. Bourgeois, Peter G. Eltgroth, Phillip B. Duffy, and William P. Dannevik Dec. 1994 14 p Presented at the 6th Workshop on Use of Parallel Processors in Meterology, Reading, England, 24 Nov. 1994 Submitted for publication
(Contract W-7405-eng-48)
(DE95-005918; UCRL-JC-119457; CONF-9411178-1) Avail: CASI HC A03/MF A01

The Climate Systems Modeling group at Lawrence Liwermore National Laboratory (LLNL) has developed a portable coupled oceanic-atmospheric general circulation model suitable for use on a variety of massively parallel (MPP) computers of the multiple instruction, multiple data (MIMD) class.

The model is composed of parallel versions of the UCLA atmospheric general circulation model, the GFDL modular ocean model (MOM) and a dynamic sea ice model based on the Hiber formulation extracted from the OPYC ocean model. The strategy to achieve parallelism is twofold. One level of parallelism is accomplished by applying two dimensional domain decomposition techniques to each of the three constituent submodels. A second level of parallelism is attained by a concurrent execution of AGCM and OGCM/sea ice components on separate sets of processors. For this functional decomposition scheme, a flux coupling module has been written to calculate the heat, moisture and momentum fluxes independent of either the AGCM or the OGCM modules. The flux coupler's other roles are to facilitate the transfer of data between subsystem components and processors via message passing techniques and to interpolate and aggregate between the possibly incommensurate meshes. ENERGIZATION AND TRANSPORT OF IONS OF IONOSPHERIC ORIGIN IN THE TERRESTRIAL MAGNETOSPHERE Final Report, 30 Apr. 1995

J. Hunter Jr. Waite 30 Apr. 1995 57 p

(Grant NAG5-1554)

(NASA-CR-197813; NAS 1.26:197813) Avail: CASI HC A04/MF A01

The work of this grant has been predominantly focused on ion outflows from two data sets: Prognoz 7 and Dynamics Explorer. The Prognoz analysis studied ion densities, temperatures, and flow velocities in the magnetotail. The work performed under this contract consisted of developing a program to load the raw data, computing the background subtraction of a strong sun pulse, and using the net count to calculate the low order moments of the distribution function. The study confirms the results of ISEE with regard to the supply of plasma from the cusp as a major source of plasmasheet plasma and goes beyond this to discuss the use of ion velocities as a way to examine the motions of the magnetotail. The abstract of the work to be reported is included as an appendix. The work on the DE/Retarding Ion Mass Spectrometer is separated into two categories: (1) classification of low-energy ion flows from high-latitudes, and (2) studies of the polar wind. Major publications resulting from this work are also included as an appendix to this report. The polar wind is in a category by itself as a result of the thermal escape of hydrogen and helium because of ambipolar diffusion through the heavier, oxygen-dominated topside ionosphere. The analysis of the polar wind reports the flux variability as a function of season, magnetic activity, etc. Much effort has been expended under this grant to complete a follow on study of the thermal structure of the polar wind. Extensive display tools and analysis software have been developed and used in an attempt to carry out this thermal analysis. The present work uses a constrained fit scheme that combines the ion densities and flow velocities derived from Chandler et al. and a spacecraft potential derived from an empirical relation to the total ion density to determine the remaining fit parameter, the ion temperature, via a least squares fit to the RIMS data. SOIL MOISTURE PREDICTION DURING FREEZE AND THAW USING A COUPLED HEAT AND MOISTURE FLOW MODEL

Susan R. Bigl and Sally A. Shoop Nov. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DA Proj. 4A1-62373-DT-08)

(AD-A289343; CRREL-94-11) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A coupled heat flow and moisture flow model (FROSTB) was used to simulate large scale freeze-thaw experiments to assess its ability to predict soil moisture conditions during freeze and thaw. The experimental data consists of temperature and soil moisture profiles through freeze-thaw cycles of a 1-m layer of frost-susceptible silty sand over roughly 2 m of gravely sand. Two experimental conditions were modeled: (1) where the soil moisture was lower than specific retention (less than 12% by weight) and no water table was present (dry case); and (2) where the soil was fairly wet and the water table was approximately in deep (wet case). During freezing, FROSTB tends to predict ice contents higher than those observed, which causes the simulated soil column to thaw slower. During thawing the predicted moisture contents in the thawed soil were close to the measured values for the wet case but were always higher than the measured moisture contents for the dry case. Possible reasons for the discrepancy are discussed. DTIC

COMPENSATED DECONVOLUTION FROM WAVEFRONT SENSING M.S. Thesis

Lori A. Thorson Dec. 1994 89 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289490; AFIT/GE/ENG/94D-29) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The U.S. Air Force has a continuing mission to obtain imagery of earth-orbiting objects. One of the means for obtaining this imagery is through the use of ground-based observatories. A fundamental problem associated with imaging objects through the atmosphere is that atmospheric turbulence inflicts a large, random aberration on the telescope which effectively limits the realizable resolution to that of a much smaller telescope. Several approaches have been taken to overcome these effects including pure post processing, pure adaptive optics, and hybrid techniques involving both adaptive optics and image post processing. One key result from past approaches is that partially compensated systems can be used in conjunction with image processing to overcome most of the optical effects of atmospheric turbulence while retaining nearly the performance of a fully compensated system. One hybrid approach is compensated deconvolution from wavefront sensing (CDWFS). This method uses wavefront sensor measurements in conjunction with short exposure images to improve the effective optical performance. This thesis formulates and executes a plan which allows fundamental questions regarding partially compensated adaptive optics performance to be answered. Specifically, imaging of extended objects using the CDWFS technique is investigated, through simulation. The simulation results demonstrate that the CDWFS technique can be used to reduce the required closed-loop bandwidth of an imaging system, permitting longer integration times in the wavefront sensor, and thus allowing dimmer objects to be imaged without the use of an artificial guidestar. A MATHEMATICAL ANALYSIS OF THE JANUS COMBAT SIMULATION WEATHER EFFECTS MODELS AND SENSITIVITY ANALYSIS OF SKY-TO-GROUND BRIGHTNESS RATIO ON TARGET DETECTION M.S. Thesis

Vincent F. Shorts Sep. 1994 80 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289629) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Janus combat simulation offers the user a wide variety of weather effects options to employ during the execution of any simulation run, which can directly influence detection of opposing forces. Realistic weather effects are required if the simulation is to accurately reproduce 'real world' results. This thesis examines the mathematics of the Janus weather effects models. A weather effect option in Janus is the sky-to-ground brightness ratio (SGR). SGR affects an optical sensor's ability to detect targets. It is a measure of the sun angle in relation to the horizon. A review of the derivation of SGR is performed and an analysis of SGR's affect on the number of optical detections and detection ranges is performed using an unmanned aerial vehicle (UAV) search scenario. For comparison, the UAV's are equipped with a combination of optical and thermal sensors. DTIC

A BATSE INVESTIGATION OF RADIATION BELT ELECTRONS PRECIPITATED BY VLF WAVES Final Report

Dayton W. Datlowe 25 Apr. 1995 18 p

(Contract NAS5-32608)

(NASA-CR-197780; NAS 1.26:197780; LMSC-F254281) Avail: CASI HC A03/MF A01

The Compton Observatory commonly encounters fluxes of energetic electrons which have been scattered from the inner radiation belt to the path of the satellite by resonant interactions with VLF waves from powerful man-made transmitters. The present investigation was motivated by the fact that in the Fall of 1993, the Gamma Ray Observatory was boosted from a 650 km altitude circular orbit to a 750 km altitude circular orbit.

This was an opportunity, for the first time, to make observations at two different altitudes using the same instrument. We have examined DISCLA data from the Burst & Transient Source Experiment (BATSE) experiment from 1 Sep. 1993 to 29 Jan. 1994. During the period of study we identified 48 instances of the satellite encountering a cloud of energetic electrons which had been scattered by VLF transmitters. We find that boosting the altitude of the circular orbit from 650 km to 750 km increased the intensity of cyclotron resonance scattered electrons by a factor of two. To search for long term changes in the cyclotron resonance precipitation, we have compared the approx. 750 km altitude data from 106 days at the end of 1993 with data at the same altitudes and time of year in 1991. The cyclotron resonance events in 1991 were three times more frequent and 25% of those cases were more intense than any seen in the 1993 data. We attribute this difference to increased level of geomagnetic activity in 1991 near the Solar Maximum. Author

MEASUREMENTS OF HF AURORAL CLUTTER USING THE VERONA AVA LINEAR ARRAY RADAR (VALAR) Report, Jun. 1990 - Jun. 1991
David S. Choi, Bertus Weijers, and Neil B. Myers Mar. 1994 25 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289442; RL-TR-94-43) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Measurements of high frequency (HF) auroral clutter using the Verona Ava Linear Array Radar (VALAR) system are presented. VALAR is an experimental HF backscatter system capable of obtaining high resolution synoptic mapping of HF auroral clutter. The receiver system includes a 700 meter long linear array, providing the high azimuthal resolution required for determining the spatial distribution of HF auroral clutter. Since the completion of the system at the end of 1989, data acquisition campaigns have been carried out on a near-monthly basis. In this report, we provide a brief description of VALAR and present preliminary measurements of three types of phenomena: ground backscatter, slant-F, and auroral backscatter. DTIC

VARIABILITY STUDY OF foF2 FOR AN EQUATORIAL STATION
J. O. Adeniyi, S. M. Radicella, and I. A. Adimula (Ilorin Univ., Nigeria.) Aug. 1994 10 p
(DE95-608080; IC-94/194) Avail: CASI HC A02/MF A01 (US Sales Only)

The deviation of hourly values of foF2 from the monthly median values was used to study the variability of foF2. The study was done for th e period of high and low solar activity. Generally the range of variation of the deviation is not dependent on solar activity. There is a tendency for positive deviation to occur on magnetically disturbed days and for negative deviation to occur on quiet days. The magnitude of the deviation does not depend on whether the day is disturbed or quiet. The correlation between Ap index and deviation of foF2 from the median value is generally poor . THe range of deviation at night is usually higher than that of the daytime for the period of high solar activity. Some seasonal effects were also observed on the deviation. DOE

DEPTH MIGRATION IN TRANSVERSELY ISOTROPIC MEDIA WITH EXPLICIT OPERATORS Ph.D. Thesis
O. Uzcategui Dec. 1994 140 p
(Contract DE-FG02-89ER-14079)
(DE95-007670; DOE/ER-14079/37; CWP-163) Avail: CASI HC A07/MF A02

The author presents and analyzes three approaches to calculating explicit two-dimensional (2D) depth-extrapolation filters for all propagation modes (P, SV, and SH) in transversely isotropic media with vertical and tilted axis of symmetry. These extrapolation filters are used to do 2D poststack depth migration, and also, just as for isotropic media, these 2D filters are used in the McClellan transformation to do poststack 3D depth migration. Furthermore, the same explicit filters can also be used to do depth-extrapolation of prestack data. The explicit filters are derived by generalizations of three different approaches: the modified Taylor series, least-squares, and minimax methods initially developed for isotropic media. The examples here show that the least-squares and minimax methods produce filters with accurate extrapolation (measured in the ability to position steep reflectors) for a wider range of propagation angles than that obtained using the modified Taylor series method. However, for low propagation angles, the modified Taylor series method has smaller amplitude and phase errors than those produced by the least-squares and minimax methods. These results suggest that to get accurate amplitude estimation, modified Taylor series filters would be somewhat preferred in areas with low dips. In areas with larger dips, the least-squares and minimax methods would give a distinctly better delineation of the subsurface structures. DOE

PRISM VALIDATION Technical Report
Robert E. Daniell, William G. Whartenby, and Lincoln D. Brown 13 Jun. 1994 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-92-C-0044)
(AD-A288476; PL-TR-94-2198; SR-1) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report describes the validation of PRISM, a parameterized, real-time ionospheric specification model, which was described in PL-TR-91-2299. Data were obtained from both analog and digital ionosondes, polarimeters measuring TEC, incoherent scatter radar (ISR), and in situ measurements of electron density, ion velocity, and auroral particle precipitation. Some of the data was used to drive the model while the remainder of the data was held in reserve for comparison with model output. We found that near ionospheric measurements (i.e., within the decorrelation length of the ionosphere), PRISM provides better than 50% improvement in f sub 0(F sub 2), N sub m(F sub 2), and TEC over the ICED, the currently operational ionospheric model at AFSFC. At distances beyond the decorrelation length, PRISM performs as well as ICED and other climatological models. We conclude that PRISM will significantly enhance the ionospheric specification capability of AFSFC. DTIC

LOW ENERGY NEUTRAL ATOM IMAGING: REMOTE OBSERVATIONS OF THE MAGNETOSPHERE
H. O. Funsten, D. J. McComas, E. E. Scime, and K. R. Moore 1995 19 p Presented at the 33rd American Institute of Aeronautics and Astronautics (AIAA) Aerospace Sciences Meeting, Reno, NV, 9-12 Jan. 1995
(Contract W-7405-eng-36)
(DE95-006342; LA-UR-95-32; CONF-950130-8) Avail: CASI HC A03/MF A01

Recent developments in detection of neutral atom imaging should enable imaging the global structure and dynamics of the terrestrial magnetosphere. The inherent technical challenge of imaging low energy neutral atoms (LENA's) with energy less than 30 keV is their separation from the tremendous UV background, to which LENA detectors are sensitive, without loss of information of LENA trajectory and energy. Three instrument concepts for separating LENA's from the background UV are presented: LENA charge conversion via transmission through an ultrathin carbon foil and subsequent electrostatic deflection, EUV grating polarizers and attenuators, and high frequency shutters. Each of these concepts can be mated to a detector section that provides both LENA imaging capability and coincidence/time-of-flight. DOE

ENERGIZATION AND TRANSPORT OF IONS OF IONOSPHERIC ORIGIN IN THE TERRESTRIAL MAGNETOSPHERE Final Report
J. H. Waite, Jr. 30 Apr. 1995 67 p Revised
(Grant NAG5-1554; SwRI Proj. 15-4258)
(NASA-CR-198618-Rev; NAS 1.26:198618-Rev) Avail: CASI HC A04/MF A01

This serves as a final report entitled Energization and Transport of Ions of Ionospheric Origin in the Terrestrial Magnetosphere. The work has been predominantly focused on ion outflows identified in two data sets: (1) Prognoz 7; and (2) Dynamics Explorer. The study analyzed ion densities, temperatures, and flow velocities in the magnetotail. The work performed under this contract consisted of developing a program to load the raw data, compute the background subtraction of a strong sun pulse, and use the net counts to calculate the low order moments of the distribution function. The study confirms the results of ISEE that the the cusp is a major source of plasmasheet plasma and goes beyond this to discuss the use of ion velocities as a way to examine the motions of the magnetotail. RELATIVISTIC ELECTRONS IN THE OUTER-ZONE: AN 11 YEAR CYCLE, THEIR RELATION TO THE SOLAR WIND
R. D. Belian, T. E. Cayton, R. A. Christensen, J. C. Ingraham, M. M. Meier, G. D. Reeves, and A. J. Lazarus 1994 15 p Presented at the 10th Taos Workshop on the Earth's Trapped Particle Environment, Taos, NM, Aug. 1994
(Contract W-7405-eng-36)
(DE95-007882; LA-UR-95-553; CONF-9408182-4) Avail: CASI HC A03/MF A01

We examine Los Alamos energetic electron data from 1979 through the present to show long term trends in the trapped relativistic electron populations at geosynchronous-earth-orbit (GEO). Data is examined from several CPA and SOPA instruments to cover the interval from 1979 through June 1994. It is shown that the higher energy electrons fluxes (E greater than 300 keV) displayed a cycle of approx. 11 years. In agreement with other investigators, we also show that the relativistic electron cycle is out of phase with the sunspot cycle. We compare the occurrences of relativistic electrons and solar wind high speed streams and determine that on the time scale of 15 years the two do not correlate well. The long-term data set we provide here shows a systematic change of the electron energy spectrum during the course of the solar cycle. This information should be useful to magnetospheric scientists, model designers and space flight planners. DOE

TESTING THE CORRELATION BETWEEN SEISMIC STRATIGRAPHY, DIAGENESIS AND PHYSICAL ROCK PROPERTIES: EVALUATION OF FLUID FLOW DURING EARLY AND LATE DIAGENESIS Progress Report, 15 Apr. 1994 - 14 Apr. 1995
J. M. Bahr 1995 5 p
(Contract DE-FG02-94ER-14439)
(DE95-008338; DOE/ER-14439/1) Avail: CASI HC A01/MF A01

This project is designed to test conceptual models of diagenesis with numerical modeling of fluid flow through the Great Bahama Bank. The finite difference code HST3D is being used to simulate fluid flow, heat transport, and solute transport through the Great Bahama Bank. Initial simulations are focussed on a 2-D profile for which the major hydrologic units and properties were chosen based on available seismic and core data. The model is being used to assess the sensitivity of flow patterns and flow rates to variations in hydraulic, thermal, and density gradients and boundary conditions. The numerical model will also be used to study the effects of sea level fluctuations and changes in permeability due to diagenesis. This will involve modification of the boundary conditions and permeability distribution to reflect conditions that are inferred to have existed during earlier diagenetic periods or as a result of sea level change. SEISMIC CONSTRAINTS ON SHALLOW CRUSTAL PROCESSES AT THE EAST PACIFIC RISE Ph.D. Thesis - MIT
Gail L. Christeson Feb. 1994 185 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-89-J-1015; NSF OCE-89-17750)
(AD-A289055; WHOI-94-02) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This thesis is concerned with understanding bow oceanic crust is emplaced at mid-ocean ridges. Nine on-bottom seismic refraction experiments are analyzed in an effort to resolve the structure of the emplacement zone of lavas and dikes at the fast-spreading East Pacific Rise. The results suggest that the volcanic section doubles in thickness within approx. 1 km of the axial summit caldera (ASC) due to the emplacement of lava that either overflows the ASC or is emplaced through eruptions outside of the ASC, and the depth to the top of the sheeted dike complex increases from approximately 130-180 m within the ASC to approximately 300-350 m a kilometer away on the flank. It is suggested that the process of dike subsidence is controlled by the axial magma chamber, which is defined as the melt lens and underlying mush zone. In addition, the results of MCS (multi-channel seismic) and wide-angle experiments over plausible velocity structures are predicted quantitatively. It is concluded that the accuracy of correlating the prominent shallow reflector observed in MCS and wide-angle data with the layer 2A/2B boundary is strongly dependent on the structure within layer 2A. MEASUREMENT AND ANALYSIS OF THE SURFACE ENERGY BUDGET FOR ARM FIELD EXPERIMENTS Final Report
Kenneth E. Kunkel (Illinois State Water Survey, Champaign, IL.) 1995 44 p Prepared in cooperation with Los Alamos National Lab., NM
(Contract W-7405-eng-36)
(DE95-007646; LA-SUB-95-33) Avail: CASI HC A03/MF A01

The objective is to conduct experiments to investigate the scaling properties of surface-atmosphere interactions and feedbacks as they relate to regional fluxes of heat and water vapor. This is part of the US Department of Energy's Atmospheric Radiation Measurement program. To achieve this objective, two field campaigns were conducted in northeastern Oregon during June 1991 and June 1992. Analysis of the data collected during these campaigns revealed the following: (1) Fluxes over a dry, semi-arid grass/brush area show only small spatial heterogeneity. (2) Fluxes over an irrigated farm were dependent on crop type and stage of development. In particular, fluxes over row crops such as potatoes and corn were very similar to each other, but somewhat different than fluxes over wheat and alfalfa. In general, higher latent and lower sensible heat fluxes were experienced over wheat and alfalfa compared to corn and potatoes. (3) Meteorological factors had a major influence on fluxes. In particular, significantly higher latent heat fluxes were experienced on days with moderate winds compared to days with light winds over the irrigated farm. This was presumably due to the advection of sensible heat from the surrounding dry rangeland. DOE

INVESTIGATION OF RIFTING PROCESSES IN THE RIO GRANDE RIFT USING DATA FROM AN UNUSUALLY LARGE EARTHQUAKE SWARM

Final Report, 1 Oct. 1992 - 30 Sep. 1993

Allan Sanford (New Mexico Inst. of Mining and Technology, Socorro, NM.), Robert Balch (New Mexico Inst. of Mining and Technology, Socorro, NM.), Hans Hartse, and Leigh House 1995 12 p
(Contract W-7405-eng-36)
(DE95-007623; LA-SUB-95-16) Avail: CASI HC A03/MF A01

Because the Rio Grande Rift is one of the best seismically instrumented rift zones in the world, studying its seismicity provides an exceptional opportunity to elucidate the active tectonic processes within continental rifts. Beginning on 29 November 1989, a 15 square km region near Bernardo, NM, produced the strongest and longest lasting sequence of earthquakes in the rift in 54 years. Our research focuses on the Bernardo swarm which occurred 40 km north of Socorro, New Mexico in the axial region of the central Rio Grande rift. Important characteristics concerning hypocenters, fault mechanisms, and seismogenic zones are discussed. DOE

DIP-MOVEOUT PROCESSING BY FOURIER TRANSFORM IN ANISOTROPIC MEDIA

J. Anderson (Mobil Oil Corp., Dallas, TX.) and I. Tsvankin Dec. 1994 39 p Presented at the 64th SEG Annual Meeting, Los Angeles, CA, 1994
(Contract DE-FG02-89ER-14079)
(DE95-007668; DOE/ER-14079/35; CWP-146P; CONF-940004-1) Avail: CASI HC A03/MF A01

Conventional dip-moveout (DMO) processing is designed for isotropic media and cannot handle angle-dependent velocity. The authors show that Hale's isotropic DMO algorithm remains valid for elliptical anisotropy but may lead to serious errors for non-elliptical transversely isotropic models, even if velocity anisotropy is moderate. Here, they present an extension of Hale's constant-velocity DMO method to anisotropic media. The DMO operator, to be applied to normal-moveout (NMO) corrected data, is based on the analytic expression for NMO velocity for dipping reflectors given by Tsvankin (1995a). Since the anisotropic DMO depends on the elastic parameters of the medium, it should be preceded by an inversion procedure designed to obtain the NMO velocity as a function of ray parameter. Another complication introduced by anisotropy is the influence of nonhyperbolic moveout not accounted for in the DMO operator. However, for spreads typical in conventional acquisition design, deviations from hyperbolic moveout for P-waves are not significant. Impulse responses and synthetic examples for typical transversely isotropic models with a vertical symmetry axis (VTI) demonstrate the accuracy and efficiency of this DMO technique. Once the inversion step has been completed, the NMO-DMO sequence does not take any more computing time than that for the generic Hale's method in isotropic media. Their anisotropic DMO operator is not limited to VTI media; it can be applied in the same fashion in symmetry planes of more complicated models such as orthorhombic. DOE

N95-28192# Colorado School of Mines, Golden, CO.

TRANSFORMATION TO ZERO OFFSET IN TRANSVERSELY ISOTROPIC MEDIA

T. Alkhalifah Feb. 1995 32 p
(Contract DE-FG02-89ER-14079)
(DE95-007669; DOE/ER-14079/36; CWP-162) Avail: CASI HC A03/MF A01

Nearly all dip moveout correction (DMO) implementations to date assume isotropic homogeneous media. Usually, this has been acceptable considering the tremendous cost savings of homogeneous isotropic DMO and considering the difficulty of obtaining the anisotropy parameters required for effective implementation. In the presence of typical anisotropy, however, ignoring the anisotropy can yield inadequate results. Since anisotropy may introduce large deviations from hyperbolic moveout, accurate transformation to zero-offset in anisotropic media should address such nonhyperbolic moveout behavior of reflections. Artley and Hale's (1994) v(z) ray tracing-based DMO, developed for isotropic media, provides an attractive approach to treating such problems. By using a ray-tracing procedure crafted for anisotropic media, the author modifies some aspects of Artley and Hale's DMO so that it can work for v(z) anisotropic media. Application of this anisotropic DMO to data from offshore Africa resulted in a considerably better alignment of reflections from horizontal and dipping reflectors in common-midpoint gather than that obtained using an isotropic DMO. Even the presence of vertical inhomogeneity in this medium could not eliminate the importance of considering the shale induced anisotropy. DOE

FOWLER DMO AND TIME MIGRATION FOR TRANSVERSELY ISOTROPIC MEDIA WITH EXPLICIT OPERATORS

J. Anderson (Mobil Oil Corp., Dallas, TX.), T. Alkhalifah, and I. Tsvankin Dec. 1994 26 p Presented at the 64th SEG Annual Meeting, Los Angeles, CA, 1994
(Contract DE-FG02-89ER-14079)
(DE95-007671; DOE/ER-14079/38; CWP-164P; CONF-940004-2) Avail: CASI HC A03/MF A01

In this report, the authors devise a Fowler-type DMO algorithm for transversely isotropic media using the analytic expression for normal-moveout velocity given by Tsvankin (1995a). Alkhalifah and Tsvankin (1995) have shown that in transversely isotropic media with a vertical axis of symmetry (VTI) the P-wave normal-moveout (NMO) velocity as a function of ray parameter can be fully described by just two parameters: the zero-dip NMO velocity V(sub nmo)(O) and the anisotropic parameter eta. In the authors extension of Fowler DMO, resampling in the frequency-wavenumber domain makes it possible to obtain the values of V(sub nmo)(O) and eta by inspecting zero-offset (stacked) panels for different pairs of the two parameters. The simplest way to reduce the range of solutions in this two-dimensional search is to obtain V(sub nmo)(O) from conventional NMO velocity analysis. Since most of the computing time is spent on generating constant-velocity stacks, the added computational effort due to the presence of anisotropy is relatively minor. Synthetic and field-data examples demonstrate that the isotropic Fowler DMO technique fails to generate an accurate zero-offset section and obtain the zero-dip NMO velocity for non-elliptical VTI models. In contrast, their anisotropic algorithm allows one to find the values of the parameters V(sub nmo)(O) and eta, and correct for the influence of transverse isotropy in the DMO processing. Combined with poststack F-K Stolt migration, this method represents a complete inversion-processing sequence capable of recovering the effective parameters of transversely isotropic media and producing migrated images for the best-fit homogeneous anisotropic model. Although the current implementation is limited to transversely isotropic media with a vertical axis of symmetry (VTI), it can be generalized for more complicated anisotropic models. DOE

A MODEL OF THE DIURNAL VARIATION IN MAGNESIUM ION DENSITY AND RADIANCE IN THE THERMOSPHERE

W. J. McNeil 6 Oct. 1994 86 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract F19628-93-C-0023)
(AD-A289824; RXR-94101; PL-TR-94-2266; SR-6) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A model has been developed to investigate the behavior of magnesium ions in the thermosphere. The model includes deposition of the atomic metal, diffusion, kinetic creation and destruction of ions, and ultimate removal of the atomic Mg. Transport of the Mg+ by electric fields is also included. A strong diurnal variation in the Mg+ profiles is observed. These profiles are transformed to radiance for conditions mimicking the GLO experiment, to which the results are compared. Key features of the GLO observations are reproduced well by the model. DTIC

CONTACT MICROMECHANICS IN GRANULAR MEDIA WITH CLAY Ph.D. Thesis
S. L. Ita Aug. 1994 194 p
(Contract DE-AC03-76SF-00098)
(DE95-006566; LBL-36515) Avail: CASI HC A09/MF A03

Many granular materials, including sedimentary rocks and soils, contain clay particles in the pores, grain contacts, or matrix. The amount and location of the clays and fluids can influence the mechanical and hydraulic properties of the granular material. This research investigated the mechanical effects of clay at grain-to-grain contacts in the presence of different fluids. Laboratory seismic wave propagation tests were conducted at ultrasonic frequencies using spherical glass beads coated with Montmorillonite clay (SWy-1) onto which different fluids were adsorbed. For all bead samples, seismic velocity increased and attenuation decreased as the contact stiffnesses increased with increasing stress demonstrating that grain contacts control seismic transmission in poorly consolidated and unconsolidated granular material. Coating the beads with clay added stiffness and introduced viscosity to the mechanical contact properties that increased the velocity and attenuation of the propagating seismic wave. Clay-fluid interactions were studied by allowing the clay coating to absorb water, ethyl alcohol, and hexadecane. Increasing water amounts initially increased seismic attenuation due to clay swelling at the contacts. Attenuation decreased for higher water amounts where the clay exceeded the plastic limit and was forced from the contact areas into the surrounding open pore space during sample consolidation. This work investigates how clay located at grain contacts affects the micromechanical, particularly seismic, behavior of granular materials. The need for this work is shown by a review of the effects of clays on seismic wave propagation, laboratory measurements of attenuation in granular media, and proposed mechanisms for attenuation in granular media. LONGTERM INFRARED CLOUD CLUTTER RESEARCH
A. C. Kruseman Oct. 1994 108 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288632; TNO-FEL-94-A094; TDCK-94-0886) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

An infrared all-sky mapper Scorpio has been developed at TNO-FEL. The system has been used to obtain 10 um sky and cloud backgrounds for about one year. The data cover an area of - 18 up to + 72 in elevation and 340 in azimuth with a spatial resolution of 0.8 mrad. The system has an absolute calibration. Data recording with 12 bit resolution, and image analysis are done with a MASSCOMP computer. The image processing is done in several steps. Non-sky areas in the images are blanked. Clutter calculations are performed in cells of 4 x 12 pixels, with local RMS as a basis. The use of a moving average in the RMS calculations diminishes the content of high clutter values. Clutter and radiance distributions are studied with elevation. Lowtran 7 calculations are performed with a model based cloud structure. These are compared with real Scorpio measurements and show good agreement. The results are discussed for a measured atmospheric height profile as well as for assumed model height profiles, based on ground level data. Scorpio images of a single day have been analysed in much detail. Clutter slope calculations show that it is an important measure for the clutter content of the sky images. An algorithm for cloudiness calculations is discussed. The detection of point targets is discussed. DTIC

WEATHER AND RADAR PROCESSOR (WARP) TEST AND EVALUATION MASTER PLAN (TEMP)
William Benner, Christopher Malitsky, William Hall, and Matthew Printy Oct. 1994 129 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288280; DOT/FAA/CT-TN94/36) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This Test and Evaluation Master Plan (TEMP) describes the Test and Evaluation (T&E) processes which will be used to ensure the Weather and Radar Processor (WARP) system meets the requirements allocated to the project in the NAS-SS-1000, volumes 1, 2, and 5, the NAS-SR-1000, and the WARP System Specification, FAA-E-To Be Determined (TBD). This TEMP defines test strategy, test requirements, and organizational roles and responsibilities and is developed in accordance with Federal Aviation Administration (FAA) Order 1810.4B and FAA-STD-O24a. This version of the TEMP addresses the testing requirements for the first two stages of WARP. This TEMP will be updated with additional detail when the WARP program Stage 1, 2, and 3 NAS Change Proposals (NCP) are developed and as the program progresses through the KDP 3 and KDP 4 phases. The original TEMP and its revisions will be submitted for approval by the Test Policy Rules Committee (TPRC). A WARP system will be deployed in all Air Route Traffic Control Centers (ARTCC) and at the Air Traffic Control System Command Center (ATCSCC). It is an Non-developmental Item (NDI)-based automated interactive meteorological data and information processing service that will serve as the primary source of real-time tactical and strategic weather data for air traffic controllers, traffic management unit (TMU) coordinators and area supervisors, meteorologists, and pilots. The WARP system will provide real-time mosaicked WSR-88D products to the air traffic controllers. DTIC

Geophysical phenomena are often characterized by smooth continuous power spectra having a domain of negative slope power law dependence. Frequently. Fourier transform analysis has been employed to synthesize scenes from pseudorandom arrays by passing the random samples through a Fourier filter having a desired correlation structure and power spectral dependency. This report approaches synthesis of three-dimensional synthetic structure by invoking autoregression analysis in conjunction with the Fourier method. Since computations that apply multidimensional fast Fourier transforms to large data arrays consume enormous resources, the goal of this study is to seek an alternative method to reduce the computational burden. Future releases of the Phillips Laboratory Strategic High Altitude Atmospheric Radiance Code (SHARC) will feature an ability to calculate structured radiance. The methods explored here provide a process that can complement or sometimes supplement methods presently being used. The three-dimensional temperature structure realizations generated by these methods were used to produce two-dimensional integrated temperature structure scenes that showed compliance with the input specifications. THE SMALL-SCALE STRUCTURE OF DISPERSING CLOUDS IN THE ATMOSPHERE Final Report, 1 Jun. 1992 - 31 May 1994
R. Ian Sykes, Robert S. Gabruk, and Douglas S. Henn Jul. 1994 91 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-92-C-0020)
(AD-A288256; ARAP-710; ARO-29369.5-GS) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The fractal properties of a plume dispersing in a turbulent velocity field have been examined using Large-Eddy Simulation results for neutral and convective boundary layers. A fractal generation technique has been developed that correctly matches a specified mean and variance distribution for the plume. The spatial correlation scale of the fractal realizations can also be specified, and the one-point probability density function can be chosen as clipped normal or lognormal. Realizations generated with the fractal technique show reasonably close resemblance to the LES results. The small-scale structure of the plume is further analyzed using multifractal techniques, and a the generation methodology is extended to incorporate unequal partitioning of the random variance during the refinement process. This procedure corresponds to the localization of small-scale energy in the turbulent cascade process which leads to an intermittent dissipation field. The multifractal spectrum of the dissipation field can be adjusted to match observations and the LES calculation results. The visual appearance of the dissipation field from the fractal/multifractal model is much more intermittent than the fractal realization, and the concentration field shows more localized small-scale fluctuations. These features give better correspondence to the LES realizations. DTIC

INDEXING MESO-BETA SURFACE WIND SITE REPRESENTATIVE Final Report
Martin E. Lee and Teizi Henmi Sep. 1994 38 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288501; ARL-TR-284) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Multiple meso-beta surface wind site data representativeness is examined in a comparison of corresponding sets of surface mesoscale model windfield predictions - with and without periodic surface data assimilation. A version of the Higher Order Turbulence Model for atmospheric Circulation (HOTMAC) is used in this study to obtain selected surface gridded windfields. Six different radiosonde initialization data sets are used to generate seven hour HOTMAC surface windfield predictions. Two series of HOTMAC simulations are executed: a control case with sparse radiosonde initialization data (less than 6 observations); and an experimental case, in which supplementary hourly surface wind observations, obtained from a consistent set of fifteen automated surface observation stations over a meso-beta scale complex terrain area, are also periodically assimilated into HOTMAC windfields by locally adjusting predicted windfield solutions toward observed conditions and correcting for mass conservation imbalances in the adjusted fields. After observation site data are interpolated from both gridded HOTMAC control and experimental surface windfield predictions, factor separation and statistical tests are used to characterize the representativeness of available surface observation stations in the modeled meso-beta scale regime. Conclusions and the implications of presented results are summarized. DTIC

FLUXES ACROSS THE WEST COAST RESOLVED BY PICKET FENCE OBSERVATIONS DURING STORMFEST M.S. Thesis
Steven J. Bolduc Sep. 1994 161 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288511) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Meteorological features that force mesoscale weather systems developed in the central U.S. often form far upstream over the data-sparse Pacific Ocean. It is hypothesized that the temporal and spatial resolution of the current rawinsonde network along the west coast may not be sufficient to detect and measure flow features moving inland. During the STORMFEST experiment in February-March 1992, a 'Picket Fence' of seven rawinsonde stations were interspersed among the seven regular rawinsonde sites from Port Hardy, British Columbia to San Diego, CA. All sites obtained observations every 3 hours rather than the normal 12 hours. The objective was to examine the feasibility of utilizing extra observations in time and space to improve upstream boundary conditions forecasting of mesoscale weather events in the central U.S. Fluxes of mass, heat, momentum, moisture, kinetic energy, and potential energy across the west coast resolved with various spatial and temporal combinations of 'Picket Fence' data were compared with the 12 hour regular site sondes as the standard. In the best case in which a wave system creased the middle of the 'Picket Fence', significantly different fluxes were calculated with the full spatial and 3 hour 'Picket Fence' observations. For other systems that crossed near the ends of the axis, only small changes were detected by the additional observations. DTIC

REPLICATOR FOR CHARACTERIZATION OF CIRRUS AND POLAR STRATOSPHERIC CLOUD PARTICLES Final Report
John Hallett and Richard G. Purcell Mar. 1995 17 p
(Grant NAG2-663)
(NASA-CR-197785; NAS 1.26:197785) Avail: CASI HC A03/MF A01

A formvar replicator for installation in an aircraft pod has been designed, built, and flight tested on the NASA DC-8. The system incorporates a deicing capability (which can be pressure activated) to enable climb out through icing situations prior to deployment. The system can be operated at preselected speeds such that data can be recorded over a period of 1 to ten hours on 200 ft of 16mm film. A x2 speed control can be used during flight. Capability exists for detection of chemical constituents by appropriate doping of formvar solution. Author

SPECTRAL ANALYSES, CLIMATOLOGY, AND INTERANNUAL VARIABILITY OF NIMBUS-7 TOMS VERSION 6 TOTAL COLUMN OZONE
J. L. Stanford (Iowa State Univ. of Science and Technology, Ames, IA.), J. R. Ziemke, R. D. McPeters, A. J. Krueger, and P. K. Bhartia Apr. 1995 84 p
(Grant NAG5-1519)
(NASA-RP-1360; Rept-95B00045; NAS 1.61:1360) Avail: CASI HC A05/MF A01

This reference publication presents selected results from space-time spectral analyses of 13 years of version 6 daily global ozone fields from the Total Ozone Mapping Spectrometer (TOMS). One purpose is to illustrate more quantitatively the well-known richness of structure and variation in total ozone. A second purpose is to provide, for use by modelers and for comparison with other analysts' work, quantitative measures of zonal waves 1, 2, 3, and medium-scale waves 4-7 in total ozone. Their variations throughout the year and at a variety of latitudes are presented, from equatorial to polar regions. The 13-year averages are given, along with selected individual years which illustrate year-to-year variability. The largest long wave amplitudes occur in the polar winters and early springs of each hemisphere, and are related to strong wave amplification during major warning events. In low attitudes total ozone wave amplitudes are an order of magnitude smaller than at high latitudes. However, TOMS fields contain a number of equatorial dynamical features, including Rossby-gravity and Kelvin waves. Author

AN OBSERVATIONAL STUDY ON THE ONSET OF THE SUMMER MONSOON OVER EASTERN ASIA IN 1979
Tao Shiyan, He Shixiu, and Yang Zufang 15 Dec. 1994 28 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289637; NAIC-ID(RS)T-0093-93) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This article analyzes the process of seasonal transition from spring to summer during the monsoon test period of May-July 1979. In the area of southern Asia and the northwestern Pacific, ten days before the outbreak of large scale summer monsoons, there was a strengthening process in upper atmosphere jet stream westerlies for the area of the southern hemisphere between 40 deg - 160 deg E in the middle latitudes. As far as the development of longitudinal circulation associated with the middle troposphere of the Southern Hemisphere as well as strengthening of cross-equatorial southerly air flows associated with lower layers of the troposphere are concerned, at this time, there was an increase in wind speed in southwesterly winds of the lower atmosphere in the tropical zones of southern Asia and the northwest Pacific. In conjunction with this, there was an expansion of ranges toward the north and an increase in tropical easterlies in the upper troposphere of the southern Asia area. Monsoon circulation patterns were strengthened, and the rainbelts of eastern China showed the appearance of seasonal northward shifts. It seems that changes in atmospheric circulation in the Southern Hemisphere have a triggering effect on the establishment of summer monsoons in the east Asian area as well as on the initiation of the pushing of them toward the north. SYNOPTIC FEATURES OF THE YUNAN RAINY SEASON BEFORE THE ONSET OF THE TROPICAL MONSOONS

Chen Yuxiang and Zhu Baozhen 15 Dec. 1994 19 p Transl. into ENGLISH from unknown Chinese periodical p 101-106 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289641; NAIC-ID(RS)T-0095-93) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This article studies a special type of weather phenomenon associated with the leeward slope of the Qinghai-Tibet Plateau - the Yunnan early rainy season. It discusses weather systems which directly create continuous precipitation as well as the special characteristics of their seasonal development. Diagnostic analysis of static energies clearly show that there are areas of difference between the Yunnan early rainy season and the arrival of the subsequent Indian monsoon with the beginning of its rainy season. It was discovered that there is a correlation between the period of the beginning of the early rainy season each year and the period of the appearance of the first storms in the Bay of Bengal. Finally, it discusses the relationships between this and seasonal changes in East Asian atmospheric circulation. DTIC

(AD-A289492; WH01-94-18) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The 1991 Acoustic Surface Reverberation Experiment (ASREX 91) took place in November and December off the coast of British Columbia. As part of this experiment, three moorings were deployed to characterize the environmental background. The moorings consisted of a meteorological/oceanographic mooring designed to measure surface meteorology, current and temperature in the upper 120 meters, and nondirectional wave parameters and two wave moorings which were instrumented with pitch-roll buoys to characterize the directional wave spectrum. This report presents results from these three moorings. The conditions seen during the experiment were extremely rough, with wind speeds at 3.4 m above the water surface reaching a maximum of 22 m/s and wave heights reaching a maximum of over 10 meters. The air-sea flux of heat was strongly cooling, and the mixed layer deepened over the course of the experiment from approximately 40 to approximately 70 meters. Spectra of the temperature showed a strong semidiurnal tidal signal associated with temperature excursions of several degrees C. The velocity signal showed strong inertial oscillations with amplitudes of 30-50 cm/s. Weaker low-frequency and semidiurnal tidal signals were also seen. The waves were very strong with significant wave heights of 5-6 meters persisting for up to 2 weeks at a time. Waves were generally out of the south or the west. DTIC

THREE OBJECTIVE INDICES FOR CLEAR-AIR TURBULENCE RECONSIDERED [DRIE OBJECTIEVE INDICES VOOR CLEAR-AIR TURBULENCE NADER BEKEKEN]

Harry Bakker Dec. 1993 33 p In DUTCH

(ISSN 0169-1708)

(KNMI-TR-160; ISBN-90-369-2047-7) Copyright Avail: Issuing Activity (Royal Netherlands Meteorological Inst., Postbus 201, 3730 AE De Bilt, Wilhelminalaan 10, Netherlands)

This technical report considers three objective forecast methods for Clean-Air Turbulence (CAT). They are the Diagnostic Richardson Tendency (DRT) and two CAT-indices such as those used in Bracknell or the NMC in Washington, respectively. The DRT-method fixes the current Richardson number on the grid points of the model and the deviation therefrom. Then a calculation is made as to how long it will take before the Richardson number exceeds the critical value 1. The Bracknell CAT-index is given by a function wherein horizontal and vertical windshear are the two variables. It provides an opportunity for 'moderate or heavy turbulence'. The NMC-index is the product of horizontal deformation and vertical windshear. This index distinguishes between 'moderate turbulence' and 'moderate or heavy turbulence'. By means of a number of case studies, we consider which method is preferable for application in the Vertical Information Model (VIM). This model is currently within the department of Scientific R & D and should be supported by meteorologists of the Aviation Meteorological Service. The case-studies make clear that the result of the DRT method should be left alone. The two other indices achieve nearly equally good results. The CAT-index of the NMC is slightly preferable for implementation in the VIM, since verification carried out at the Canadian Newfoundland Weather Center indicated that the NMC-index scores somewhat better than the Bracknell CAT-index. THE DISTRIBUTION OF CLOUD COVER OVER THE FORMER USSR AS DERIVED FROM THE RIHMI 223-STATION 3-HOURLY METEOROLOGICAL DATABASE

D. P. Kaiser, R. S. Vose, T. R. Karl (National Climatic Data Center, Asheville, NC.), and V. N. Razuvaev (Research Inst. of Hydrometeorological Information, Dbninsk, Russia. Obninsk, Russia.) 1995 6 p Presented at the 75th Annual Meeting of the American Meteorological Society: Diamond Anniversary, Dallas, TX, 15-20 Jan. 1995
(Contract DE-AC05-84OR-21400)
(DE95-007046; CONF-950124-5) Avail: CASI HC A02/MF A01

In recent years a great deal of meteorological and climatological data has been exchanged between the two principal climate data centers of the United States and the former Soviet Union: the National Climatic Data Center (NCDC), in Asheville, North Carolina, and the Research Institute of Hydrometeorological Information (RIHMI) in Obninsk, Russia. This was accomplished via Working Group VIB (Influence of Environmental Changes on Climate) of the bilateral initiative known as the Agreement on Protection of the Environment, established on May 23, 1972 by the United States and the USSR. One of the key datasets compiled by RIHMI includes 3-hourly meteorological observations from 223 USSR stations for the period 1966-83. RIHMI has chosen to use daily and hourly data from these stations as the basis for considerable climate research efforts. These data (hereafter referred to as the RIHMI database) will soon be made available by both NCDC and the Department of Energy's Carbon Dioxide Information Analysis Center (CDIAC) in Oak Ridge, Tennessee. The data have undergone extensive quality assurance checks at RIHMI, NCDC, and CDIAC. The data contain observations of some 22 meteorological variables, including near-surface air temperature, sea level pressure, precipitation amount, weather type, and total cloud cover. This study uses the RIHMI database to examine the spatial distribution of total cloud cover over the former USSR (hereafter referred to as the USSR). In this initial assessment, we focus on comparing our results with total cloud cover data presented in the atlas: Global Distribution of Total Cloud Cover and Cloud Type Amounts Over Land for the common data period 1971-81. ADVANCES IN SCIENTIFIC VISUALIZATION

N. Max and R. Crawfis 11 Jan. 1995 6 p Presented at the SPIE '95: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract W-7405-eng-48)
(DE95-008065; UCRL-JC-119460; CONF-950226-24) Avail: CASI HC A02/MF A01

This paper discusses scientific visualization of scalar and vector fields, particularly relating to clouds and climate modeling. One cloud rendering method applies a 3-D texture to cloudiness contour surfaces, to simulate a view from outer space. The texture is advected by the wind flow, so that it follows the cloud motion. Another technique simulates multiple scattering of incident light from the sun and sky. This paper also presents a simulation of the microscopic cross-bridge motion which powers muscle contraction. It was rendered by ray-tracing contour surfaces of summed Gaussian ellipsoids approximating the actin and myosin protein shapes. DOE

A STUDY OF LIGHTNING IN WINTER THUNDERSTORMS AND THE ANALYSIS OF THUNDERSTORM OVERFLIGHT DATA Final Report, Oct. 1987 - Oct. 1994

Marx Brook 20 May 1995 13 p
(Grant NAG8-066)
(NASA-CR-198577; NAS 1.26:198577) Avail: CASI HC A03/MF A01

Thunderstorms and the activities associated with them was the emphasis of this final report. The primary goal of the investigation of the dynamics, microphysics, and the electrical properties of tropical thunderstorms, was to understand the process or processes which initiate the precipitation in various convective clouds. A concept that the degree of atmospheric instability that determines the updraft velocity is different between those storms that generate electrical activity and those that do not. This is apparent in temperate latitudes, but in tropical regions, little knowledge of these interactions is available. Several ground monitoring stations have been set up and, along with a waveform recorder at one of the stations, the data collected from these stations will be analyzed in conjunction with other data collected from ship and airborne radars and airborne in situ measurements of electrical activity in coordination with the TOGA-COARE program. Two neural networks and their theoretical backgrounds are described. In the first part of this report the neural networks are applied to an artificial linear regression problem, where the underlying regression is precisely known and where study and test data can be generated. In the second part these neural networks are applied to practical data from meteorological practice with a preponderant linear connection and a weak interaction between tow predictors. In the third part of the report the learning capability is investigated. This investigation concentrates especially on the characteristics of neural networks in comparison with classical statistics. THE PROGRAM FOR CALCULATING SUNSHINE DURATION FROM GLOBAL RADIATION [HET PROGRAMMA VOOR BEREKENING VAN ZONNESCHIJNDUUR UIT GLOBALE STRALING]

U. Bergman 1993 25 p In DUTCH
(ISSN 0169-1708)
(KNMI-TR-158; ISBN-90-369-2045-0) Copyright Avail: Issuing Activity (Royal Netherlands Metheorological Inst., Postbus 201, 3730 AE De Bilt, Wilhelminalaan 10, Netherlands)

For years the KNMI (Koninklijk Nederlands Meteorologisch Instituut) has entered hourly values of sunshine duration for a large number of Netherlands observation stations into a climatological database. These values serve as the basis for all kinds of climatological products. In particular these products involve overviews with daily, monthly, or yearly totals of sunshine duration for the stations. Until recently the Campbell-Stokes autograph served as the operational measuring instrument. The need for automatization arose with respect to the measurement of sunshine duration.

This need was prompted in large measure by the finding of the World Meteorological Organization (WMO) in 1989, when discussing the case of direct radiation of an area on a surface perpendicular to the sun's radiation exceeding a value of 120 W/sq m. Measurements using a Campbell-Stokes instrument in this connection were characterized as obsolete and not objective. It was obvious that a direct radiation meter was needed for the measurement of sunshine duration. It was decided to allow the calculation of sunshine duration from global radiation values. The Campbell-Stokes measurement net has been reduced to 11 locations. The Campbell-Stokes measurements will be continued for the present, with an eye to the comparison of the new method with the old. The data will be stored at the Climatological Service. Derived from text

(DE95-008393; ARM-95-001) Avail: CASI HC A04/MF A01

The Southern Great Plains (SGP) Cloud and Radiation Testbed (CART) site is designed to help satisfy the data needs of the Atmospheric Measurement (ARM) Program Science Team. This document defines the scientific priorities for site activities during the six months beginning on January 1, 1995, and also looks forward in lesser detail to subsequent six-month periods. The primary purpose of this Site Scientific Mission Plan is to provide guidance for the development of plans for site operations. It also provides information on current plans to the ARM functional teams (Management Team, Experiment Support Team (EST), Operations Team, Data Management Team (DMT), Instrument Team (IT), and Campaign Team) and serves to disseminate the plans more generally within the ARM Program and among the members of the Science Team. This document includes a description of the operational status of the site and the primary envisaged site activities, together with information concerning approved and proposed Intensive Observation Periods (IOPs). Amendments will be prepared and distributed whenever the content changes by more than 30% within a six-month period. The primary users of this document are the site operator, the site scientist, the Science Team through the ARM Program Science Director, the ARM Program Experiment Center, and the aforementioned ARM Program functional teams. This plan is a living document that will be updated and reissued every six months as the observational facilities are developed, tested, and augmented and as priorities are adjusted in response to developments in scientific planning and understanding. SYSTEMATIC AND INTEGRATED APPROACH TO TROPICAL CYCLONE TRACK FORECASTING. PART 1: APPROACH OVERVIEW AND DESCRIPTION OF METEOROLOGICAL BASIS Interim Report, Jan. - Dec. 1994

Lester E. Carr, III and Russell L. Elsberry Jan. 1995 285 p Sponsored by the Office of Naval Research Marine Meteorology Program Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A291775; NPS-MR-94-002) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A systematic and integrated approach to tropical cyclone (TC) track forecasting is proposed. The approach is based on the premise that TC forecasters can improve upon dynamical track forecasts generated by numerical models and other objective guidance, if the forecasters are equipped with: (1) a meteorological knowledge base of conceptual models that organizes a wide array of scenarios into a relatively few recurring, dynamically-related situations; and (2) a knowledge base of numerical model TC forecast traits and objective aid traits that is organized around the meteorological knowledge base. The approach is systematic because it includes a methodology for consistently applying the two knowledge bases to generate the official track forecast. The approach is also integrated because the meteorological knowledge base includes motion-relevant characterizations of environment structure, characterizations of TC structure (intensity and size), and motion-affecting alterations of the environment structure caused by various interactions between the TC and the environment. MEASUREMENTS OF DAYTIME AND UPPER TROPOSPHERIC WATER VAPOR PROFILES BY RAMAN LIDAR

S. E. Bisson and J. E. M. Goldsmith 1995 4 p Presented at the 6th Optical Society of America (OSA) Meeting on Remote Sensing of the Atmosphere, Salt Lake City, UT, 6-9 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-007640; SAND-95-8503C; CONF-950277-2) Avail: CASI HC A01/MF A01

One of the most important atmospheric constituents needed for climate and meteorological studies is water vapor. Water vapor plays an important role in driving atmospheric circulations through latent heat release and in determining the earth's radiation budget, both through its radiative effects (water vapor is the major greenhouse gas) and cloud formation. The vertical distribution of water vapor is particularly important because it not only determines convective stability but radiative effects are also strongly altitude dependent. At present, considerable controversy exists over the nature of the vertical redistribution of water vapor in a changing climate, and particularly the distribution of water vapor in the upper troposphere. Understanding upper tropospheric moistening processes such as deep convection are therefore of prime importance in addressing the water vapor feedback question. A powerful, proven technique for the continuous measurement of nighttime water vapor profiles (in clear skies or up to the lowest cloud level) with high spatial and temporal resolution is Raman lidar. As part of the U.S. Department of Energy's (DOE) Atmospheric Radiation Measurement (ARM) program, a high performance dual field-of-view (fov), narrowband Raman lidar system capable of both daytime and nighttime operation has been developed. In this paper, the Sandia Raman lidar system is discussed along with its application to two problems of current interest: daytime tropospheric water vapor profile measurements and upper tropospheric water vapor. We present recent measurements of upper tropospheric moisture made at the DOE Cloud and Radiation Testbed site (CART) in Oklahoma. Recent daytime measurements are also presented. DOE

CLOUD CLASSIFICATION USING WHOLE-SKY IMAGER DATA

K. A. Buch, Jr. and Chen-Hui Sun 1995 7 p Presented at the 9th Symposium on Meterological Observations and Instrumentation, Charlotte, NC, 27-31 Mar. 1995
(Contract DE-AC04-94AL-85000)
(DE95-006501; SAND-95-8475C; CONF-9503104-1) Avail: CASI HC A02/MF A01

Clouds are one of the most important moderators of the earth radiation budget and one of the least understood. The effect that clouds have on the reflection and absorption of solar and terrestrial radiation is strongly influenced by their shape, size, and composition. Physically accurate parameterization of clouds is necessary for any general circulation model (GCM) to yield meaningful results. The work presented here is part of a larger project that is aimed at producing realistic three-dimensional (3D) volume renderings of cloud scenes, thereby providing the important shape information for parameterizing GCMs. The specific goal of the current study is to develop an algorithm that automatically classifies (by cloud type) the clouds observed in the scene. This information will assist the volume rendering program in determining the shape of the cloud. Much work has been done on cloud classification using multispectral satellite images. Most of these references use some kind of texture measure to distinguish the different cloud types and some also use topological features (such as cloud/sky connectivity or total number of clouds). A wide variety of classification methods has been used, including neural networks, various types of clustering, and thresholding. The work presented here utilizes binary decision trees to distinguish the different cloud types based on cloud feature vectors. DOE

SEVERE WEATHER GUIDE MEDITERRANEAN Final Report

Dennis C. Perryman, Richard D. Gilmore, and Ronald E. Englebretson Sep. 1994 45 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289829; NRL/PU/7541-94-0016) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This handbook for the port of Istanbul, one in a series of severe weather guides for Mediterranean ports, provides decision-making guidance for ship captains whose vessels are threatened by actual or forecast strong winds, high seas, restricted visibility or thunderstorms in the port vicinity. Causes and effects of such hazardous conditions are discussed. Precautionary or evasive actions are suggested for various vessel situations. The handbook is organized in four sections for ready reference: general guidance on handbook content and use; a quick-look captain's summary; a more detailed review of general information on environmental conditions; and an appendix that provides oceanographic information. HINDCASTING WIND-DRIVEN ANOMALIES USING REDUCED-GRAVITY GLOBAL OCEAN MODELS WITH 1/2 DEG AND 1/4 DEG RESOLUTION Final Report
E. Joseph Metzger, Harley E. Hurlburt, Gregg A. Jacobs, and John C. Kindle 30 Sep. 1994 24 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(RM35G93)
(AD-A289060; NRL/FR/7323-93-9444) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Global versions of the Navy Layered Ocean Model are used to hindcast wind-driven oceanic anomalies. These versions are reduced-gravity with the lowest layer infinitely deep and at rest. Grid resolutions of 0.5 (1/2 deg) and 0.25 (1/4 deg) are used. Winds at the 1000-mbar level from the European Centre for Medium-Range Weather Forecasts are used as forcing functions for the models over the 1981-1990 time frame. The models' ability to reproduce wind-forced anomalies on intraseasonal to interannual time scales is studied by comparing the model solutions with various observational data sets. These include satellite altimetry, drifting buoys, and island/coastal sea-level stations. The effects of varying horizontal and vertical resolution are also investigated. The models are able to hindcast many of the wind-driven anomalies. The best correlation is found in the tropical regions where the oceanic response to atmospheric forcing is the most rapid. At midlatitudes, mesoscale flow instabilities are a major source of oceanic anomalies. However, the resolution of the global models used here is not adequate for these instabilities. In addition, the reduced gravity models lack the barotropic mode and the realistic bottom topography, both of which can play an important role in the flow instabilities. A technique that gives maps showing the fraction of variability in the hindcast that is deterministic (in response to atmospheric forcing) and the fraction that is not deterministic (due to flow instabilities) is also demonstrated. Sorensen (California Univ., Santa Barbara, CA.), Daniel A. Konnoff (California Univ., Santa Barbara, CA.), Eric A. Brody (California Univ., Santa Barbara, CA.), James L. Mueller (San Diego State Univ., San Diego, CA.), Curtiss O. Davis (Naval Research Advisory Committee, Washington, DC.), and W. Joseph Rhea (Naval Research Advisory Committee, Washington, DC.) et al Feb. 1995 63 p
(NASA-TM-104566-Vol-26; Rept-95B00081-Vol-26; NAS 1.15:104566-Vol-26) Avail: CASI HC A04/MF A01

The accurate determination of upper ocean apparent optical properties (AOP's) is essential for the vicarious calibration of the sea-viewing wide field-of-view sensor (SeaWiFS) instrument and the validation of the derived data products. To evaluate the role that data analysis methods have upon values of derived AOP's, the first Data Analysis Round-Robin (DARR-94) workshop was sponsored by the SeaWiFS Project during 21-23 July, 1994. The focus of this intercomparison study was the estimation of the downwelling irradiance spectrum just beneath the sea surface, E(sub d)(0(sup -), lambda); the upwelling nadir radiance just beneath the sea surface, L(sub u)(0(sup -), lambda); and the vertical profile of the diffuse attenuation coefficient spectrum, K(sub d)(z, lambda). In the results reported here, different methodologies from four research groups were applied to an identical set of 10 spectroradiometry casts in order to evaluate the degree to which data analysis methods influence AOP estimation, and whether any general improvements can be made. The overall results of DARR-94 are presented in Chapter 1 and the individual methods of the four groups are presented in Chapters 2-5. The DARR-94 results do not show a clear winner among data analysis methods evaluated. It is apparent, however, that some degree of outlier rejection is required in order to accurately estimate L(sub u)(0(sup -), lambda) or E(sub d)(0(sup -), lambda). Furthermore, the calculation, evaluation and exploitation of confidence intervals for the AOP determinations needs to be explored. That is, the SeaWiFS calibration and validation problem should be recast in statistical terms where the in situ AOP values are statistical estimates with known confidence intervals. Author

THE EFFECT OF INFRARED SEA SURFACE TEMPERATURE MEASUREMENTS ON EVAPORATION DUCT HEIGHT ESTIMATION

P. A. Frederickson, K. L. Davidson, and F. K. Jones 30 Nov. 1994 21 p Sponsored by Naval Oceanographic Office Limited Reproducibility: More than 20% of this document may be affected by microfiche quality (AD-A289045; NPS-MR-94-003) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In September 1994 personnel from the Naval postgraduate School (NPS) and the Naval Oceanographic Office (NavO) conducted an experiment off the coast of Mississippi to determine the accuracy of infrared sea surface temperature (SST) measurements made from a small boat1 and the effect of these measurements on estimating the evaporation duct height (z*). It was found that infrared SST measurements are highly accurate, agreeing closely with SST measurements made by other methods, and that a small relative error in the SST measurements can lead to large errors in z* estimates. However, it is difficult to predict the effect a given error in SST will have on the resulting z* estimate, due to the complex relationship between SST and z*. DTIC

TEMPORAL AND SPATIAL DECORRELATION SCALES OF THE YELLOW SEA THERMAL FIELDS M.S. Thesis

Susan K. Wells Sep. 1994 116 p Sponsored by Naval Oceanographic Office Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288617) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Historically, studies on decorrelation scales have been conducted in the deep ocean waters. As the Navy shifts its interest toward the less understood shallow water regions, decorrelation scales need to be computed in order to use formerly deep water models such as the Optimum Thermal Interpolation System (OTIS) for shallow water regions such as the Yellow Sea. A data set containing over 35,000 temperature profiles from 1929 to 1991 was obtained from the Naval Oceanographic Office's MOODS data set. The winter and summer seasons provide realistic results. Winter has the smallest decorrelation scales of all the seasons, approximately 15 days and 165 km. Summer shows that there are different decorrelation scales between the surface and at depth. The surface has scales of 12.3 days and 251 km while at depth the scales are approximately 16.5 days and 163 km. An observational sampling network design is suggested for future sampling of the region. Spring and fall provide mixed results which may be due to the irregularities in time and space of the data set or to the very complex forcing mechanisms found in the region. Overall, this study gives a ground work for better refinement of decorrelation scales and thus, the ability to assess the conversion of deep water models to shallow water regions. DTIC

INFRARED FIELD MEASUREMENTS OF SEA SURFACE TEMPERATURE: ANALYSIS OF WAKE SIGNATURES AND COMPARISON OF SKIN LAYER MODELS

Christopher J. Zappa Aug. 1994 276 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts NAGw-2888; N00014-91-J-1951; N00014-93-1-1326)
(NASA-CR-197849; NAS 1.26:197849; AD-A288579; APL-UW-TR-9412)
Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Infrared field measurements of ocean skin temperature made aboard the R/P FLIP in January of 1992 approximately 400 nautical miles off the coast of San Diego are presented. An extensive literature review accompanies these measurements probing the fundamentals of air-sea interaction, electromagnetics, and free-surface flows. A thin layer at the air-sea interface, known as the ocean skin layer, transfers heat by molecular conduction. The skin layer is on the order of a mm and typically 0.1 to 0.5 C cooler than the water just below for conditions of net heat flux from the ocean to the atmosphere. Two surface-piercing cables hanging from FLIP's port boom, each 1 cm in diameter, provided a disturbance of the skin layer mixing the warmer water from below up to the surface. Employing an infrared imager, we detected the temperature variations, tracked the signatures and quantified the spatial and thermal changes in time of these artificial disturbances, which were on the order of a meter. This unique method of visualizing turbulence at an air-water interface provides a direct measurement of the bulk-skin temperature difference. The recovery rate of the skin layer was found to be directly related to the level, or strength, of the disruption under low wind speed conditions (approximately 2 m/s). At moderate wind speeds (approximately 7 m/s), both the natural (breaking waves) and artificial (wakes) disturbances recovered within 2 s compared to an extrapolated recovery time of up to approximately 120 s under low wind speeds for the wake signatures. The difference is primarily a function of the net heat flux and sublayer thickness, which relate directly to the existing environmental conditions (e.g., turbulence intensity, sea state, wind speed). DTIC

DEEP CONVECTION IN THE MEDITERRANEAN SEA M.S. Thesis

Bernard H. Arata Sep. 1994 85 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288497) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

It is now understood that deep convection in the ocean plays a dominant role in determining the climate of the world's oceans. Recent theoretical advances in explaining oceanic convection need to be tested by real observations. Satellite observations of deep convection regions may be a promising new tool in studying this phenomenon. This thesis examines deep convection events in two ways: To assess the characteristic elements of a deep convection event using two different prediction models based upon the turbulent kinetic energy budget. To attempt to observe deep convection phenomena signals in altimeter data. In 1987, a deep convection event was observed in the northwestern Mediterranean Sea (Schott and Leaman 1991). These data, combined with GEOSAT altimeter data, were used to verify the Kraus and Turner and the Naval Postgraduate School mixed layer model predictions of the time evolution of temperature, salinity and mixed layer depth. Both models predicted final values similar to the observations, but model tuning was required to reproduce the observed rapid mixed-layer deepening. The interpolated altimeter field does not allow identification with confidence of the Mediterranean convection area. However, a locally persistent feature and the mean winter sea surface topography field agree with in-situ observations and do provide some indication about where and when the convection process occurs. CALCULATION OF SUSPENDED SEDIMENT TRANSPORT BY COMBINED WAVE-CURRENT FLOWS Final Report

Palitha N. Wikramanayake and Ole S. Madsen Nov. 1994 219 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289368; WES/CR/DRP-94-7) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The objective of this study was to investigate the application of simple eddy viscosity models, developed for wave-current interaction, to the problem of sediment suspension and transport. A review of existing models is given; however, it is pointed out that all models compute suspended sediment transport by interacting the product of mean concentration and mean velocity. Because recent field experiments indicate that time-varying quantities may dominate the sediment flux due to mean components, the model described in this report calculates time-varying components of the concentration along with the mean flow component. The report describes the governing equations and boundary conditions, the process used to select an eddy viscosity model for hydrodynamics of wave-current interaction, and the determination of a resuspension coefficient. Detailed summaries of model development and the solution scheme are provided, as well as example calculations using the computer program WCSTRANS. A source listing of the computer model is included. VERY LOW FREQUENCY SEISMO-ACOUSTIC NOISE BELOW THE SEA FLOOR (0.2-10 Hz) Ph.D. Thesis - MIT
Christopher Robert Bradley Feb. 1994 249 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-89-C-0018; N00014-89-J-1012; N00014-90-C-0098; N00014-90-J-1493; N00014-93-1-1352)
(AD-A289164; WHOI-94-09) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The sources and propagation of sub-seafloor microseismic noise between 0.2 and 10 Hz are investigated. There are two fundamental interface wave modes for noise propagation in the crust: the Stoneley and pseudo-Rayleigh wave. In soft bottoms only the Stoneley interface wave can exist. Longer wavelength noise propagates as Rayleigh and Stoneley modes of the ocean + crust waveguide. During the Low Frequency Acoustic Seismic Experiment (LFASE) a borehole array (SEABASS) was deployed in the Blake Bahama Basin in DSDP Hole 534B. The 0.3 Hz microseism peak is nearly invariant with depth at a level of 65 and 75 dB rel 1 (nm/s(exp 2))(exp 2)/Hz for the vertical and horizontal components respectively. At 100 m depth, the mean microseismic noise levels above 0.7 Hz are 10 dB and 15-20 dB quieter for the vertical and horizontal components respectively. Higher modes in the spectra show narrow bandwidth depth variability in the noise field. Particle motion analysis further verifies that noise propagates through the array as Rayleigh/Stoneley waves. Numerical modeling for hard and soft bottom environments shows that heterogeneities on the order of a seismic wavelength radiate energy into the water column and convert acoustic waves in the water into small wavelength Stoneley waves observed at the borehole. OBSERVATIONS OF NEAR-BOTTOM FLOW IN A WAVE-DOMINATED NEARSHORE ENVIRONMENT Technical Report
J. J. Fredericks, John H. Trowbridge, and Yogesh C. Agrawal Feb. 1994 168 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-92-J-12300)
(AD-A289331; WHOI-94-04) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

To provide observational data for analysis of near-bottom, wave-induced flows, a downward-looking laser Doppler velocimeter (LDV) was deployed to profile the near-bed velocity structure of a six meter water column at a site just outside the surfzone off the coast of North Carolina. Ninety second 'snap-shots' of the velocity at six elevations below 20 cm above bottom were measured at 25 Hz while pressure was concurrently measured at 126 cm above bottom. The near-bottom data were supplemented with a benthic acoustic stress sensor (BASS) at approximately 20 cm above bottom which concurrently measured velocity components at 10 Hz. The purposes of this report are to document the collection, processing and archival of these data and to present the profiles for evaluation. DTIC

To enhance collaboration between researchers who model upper ocean biological/physical processes, a workshop was held at WHOI on June 7-12, 1993. The workshop was part of our on-going URIP project entitled 'Modeling Biological-Physical Interactions: A Population Biological Approach' sponsored by ONR (Grant N00014-92-J-1527). The two principal goals of the workshop were to: (1) identify critical Problems related to mixed-layer biological-physical models; and (2) develop approaches for solving these problems. The workshop was organized into two parts to address these goals. The first part, held over the first day and a half, included three overview presentations given in plenary followed by working groups, organized along disciplinary lines, to identify critical issues. The second part of the workshop consisted of working groups, organized across disciplines, using 'hands-on' modeling to address critical aspects of coupled biological-physical models. Several coupled models were presented and/or developed at the workshop addressing specific aspects of both the biological and physical dynamics. These aspects included the different mixed-layer formulations, a structured grazer population model, and an allometric food-web model including microbial-loop dynamics. DTIC

(AD-A289050; NRL/FR/7322-94-9601) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Naval Research Laboratory developed a coupled ice-ocean model that simulates ice-ocean interactions in response to atmospheric forcing. This model couples the U.S. Navy's Polar Ice Prediction System ice model, which is based on the Hibler ice model, to a diagnostic version of the Bryan-Cox three-dimensional ocean circulation model. A 6-yr simulation was performed using daily atmospheric data from the Fleet Numerical Meteorology and Oceanography Center's Naval Operational Global Atmospheric Prediction System (NOGAPS) for the years 1986 through 1991. Interannual variability in most NOGAPS fields was large. Ice thickness and ice concentration changes responded directly to fluctuations in surface forcing fields. The thinnest ice of the simulation occurred in 1989, 1990, and 1991. In 1990 and 1991, the surface air temperatures were warm compared to the other years, but in 1989 the net longwave radiation from NOGAPS was anomalously large in the summer. In the summer, solar and sensible heat fluxes are the strongest forcing fields, and they add heat into the ice-ocean system causing ice to melt. In the fall, solar heating diminished and the combination of sensible plus latent fluxes, along with longwave radiation, caused a dramatic cooling that resulted in ice growth. In the winter, the sensible heat flux added heat into the system, but the combination of latent heat flux and longwave cooling dominated; the result was further ice growth. Winds have a pronounced effect on ice growth/melt by directly altering the sensible and latent heat fluxes and by indirectly affecting all heat fluxes by altering the distribution of ice cover and open water. Ice advection may account for more than half of the change in ice thickness in any given month when the winds are strong. DTIC

[AN IN SITU EVALUATION OF TOPEX/POSEIDON ALTIMETRIC MEASUREMENTS VERSUS MEAUREMENTS MADE BY MOORINGS AND INVERTED ECHO SOUNDERS FOR SEA SURFACE HEIGHT] Final Report
[1994] 25 p
(Grants NAG5-2058; JPL-958123)
(NASA-CR-198621; NAS 1.26:198621) Avail: CASI HC A03/MF A01

The classical method of observing the sea surface height has been to make shipboard measurements of the vertical - density profile, and then calculating the surface height relative to a deeper reference surface. Two methods (a moored vertical string of instruments and an inverted echo sounder) were subsequently developed to obtain longer time in situ measurements. The first of these can be thought of as an extension of the discrete bottle hydrocast while the second integrates acoustically over the water column. One purpose of this note is to compare the result when coincidental observations are made by these two methods. This was done at two sites in the western tropical Pacific. Two inverted echo sounders were deployed alongside two enhanced TOGA-COARE moorings to be used in an in situ evaluation of TOPEX/Poseidon altimetric measurements of sea surface height. The mooring and inverted echo sounder data reproduced one another, at low frequency, with a correlation of 0.93 and 0.95 and the altimeter correlated with each of the above values ranging from 0.84 to 0.94. It is concluded that the altimetric measurements are

statistically equivalent to the in situ measurements in the area of study.

ON THE PERSISTENCE OF THE OCEANIC BACKGROUND OF APPARENT SEA LEVEL CHANGES IN THE BALTIC SEA
V. I. Bogdanov (Academy of Sciences, USSR, Moscow, USSR.), M. Yu. Medvedev (Academy of Sciences, USSR, Saint Petersburg, USSR.), and K. A. Taybatorov (Academy of Sciences, USSR, Moscow, USSR.) 1994 23 p
(ISSN 0355-1962)
(Rept-94:5; ISBN-951-711-181-9) Avail: CASI HC A03/MF A01

Evidence of the persistence of a time series representing the noise background of apparent (land uplift-caused) sea level changes in the Baltic Sea has been revealed. The results were obtained by analyzing tide-gauge data of the Stockholm and Kronstadt sea level stations provided by historical series for a 1.5-century period. The physical nature of this phenomenon and its significance were discussed in connection with geodetic studies. The necessity of performing similar calculations for all the sea level stations included in the observational network of the geodetic and geodynamic International 'Baltic Sea Level' Project as well as for coastal stations in the Danish Straits and North Sea was emphasized. This document provides brief reports, or case studies, on a number of investigations sponsored by the Calibration and Validation Team (CVT) within the Sea-viewing Wide Field-of-view Sensor (SeaWiFS) Project. Chapter I describes a comparison of the irradiance immersion coefficients determined for several different marine environmental radiometers (MERs). Chapter 2 presents an analysis of how light absorption by atmospheric oxygen will influence the radiance measurements in band 7 of the SeaWiFS instrument. Chapter 3 gives the results of the second ground-based solar calibration of the instrument, which was undertaken after the sensor was modified to reduce the effects of internal stray light. (The first ground-based solar calibration of SeaWiFS is described in Volume 19 in the SeaWiFS Technical Report Series.) Chapter 4 evaluates the effects of ship shadow on subsurface irradiance and radiance measurements deployed from the deck of the R/V Weatherbird 11 in the Atlantic Ocean near Bermuda. Chapter 5 illustrates the various ways in which a single data day of SeaWiFS observations can be defined, and why the spatial definition is superior to the temporal definition for operational usage. TOMOGRAPHIC OBSERVATIONS OF DEEP CONVECTION AND THE THERMAL EVOLUTION OF THE GREENLAND SEA GYRE 1988-1989 Ph.D. Thesis - MIT
Ryszard A. Pawlowicz Feb. 1994 175 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contracts N00014-92-J-1291; N00014-91-J-1246)
(AD-A289104; WHOI-94-08) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The Greenland Sea Gyre is studied using results from the 1988-89 Greenland Sea Tomography Experiment. Thermal evolution of the gyre center divides into three periods: a preconditioning phase, a deep mixing phase, and a restratification phase. During preconditioning, ice forms and rejects brine into the surface waters, enabling destabilization of the water column. The onset of the deep mixing phase occurs after ice formation in the gyre center stops, resulting in an area of open water where large heat fluxes can occur. In surrounding regions, including the odden region to the south, ice is still being formed, and the mixed layer does not deepen significantly. The effects of advection are deduced from heat and salt budgets, and appear to be important only during the restratification phase for intermediate depths, and only during the summer for the surface waters. Dynamical processes for bringing the Arctic Intermediate Water (AIW) to the surface in order to form deep water are not needed in this scenario, rather the surface waters are modified until they match the density of the AIW after which surface cooling drives convection. [RESEARCH ACTIVITIES ON SOMATOSENSORY (SI) CORTICAL NEURONS] Annual Report, 1 Jul. 1993 - 30 Jun. 1994
Randall J. Nelson 21 Nov. 1994 84 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Grant AF-AFOSR-0333-91)
(AD-A288794; AF-AFOSR-0763-94-TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Three research goals were accomplished during this third year. (1) Analysis of data indicated that the responsiveness of primary somatosensory (SI) cortical neurons is 'unattended' if when behavioral conditions become unpredictable. This observation fits with the hypothesis that during stereotyped behavior, neuronal responsiveness is gated so that the CNS may partially engage in other activities. (2) SI cortical neurons that respond to vibratory go-cues for wrist movement with the greatest fidelity have their activity modulated just prior to movement onset. This observation fits with the hypothesis that prior to active movement, sensory inputs that are no longer behaviorally relevant are gated so as not to interfere with monitoring movement parameters by the primate CNS. (3) SI cortical neurons that may bind together other SI neurons with their rhythmic activity have this activity disrupted at go-cue onset and just prior to movement onset. This observation fits with the hypothesis that prior to behaviorally significant events, the activity of these neurons that may tonically gate other SI neurons is suppressed to allow the monitoring sensory events and the initiation of movements. This study was designed to investigate the interaction of staphylococcal enterotoxins and exfoliative toxins with leukocytes and to establish baseline information on the consequences of those interactions. Receptor-ligand interactions were characterized and a new non-major histocompatibility complex (MHC) class 2 receptor on the surface of macrophages was discovered. Once these data were at hand, we also prepared an anti-idiotype antibody to class 2 MHC and have used it to inhibit interaction of toxins with their cognate receptor on macrophage surfaces. These studies have resulted in the publication of 31 manuscripts and 7 published abstracts.

Virtually every antifungal agent in use intercedes some aspect of sterol synthesis or function. Ergosterol is the principal sterol in fungi, while cholesterol is the most abundant sterol in vertebrates. Research in our laboratory has shown that the structural differences in ergosterol, in comparison to cholesterol, have distinctive biochemical and physiological effects in fungi. Under the completed contract we have shown that as the sterol composition of sterol auxotrophic strains of Saccharomyces cerevisiae is altered there is disturbance of the mating efficiency of the strains. The normal sterol, ergosterol, mediates a 30-fold higher productive mating efficiency in the auxotrophs than when the cells are supplied with stigmasterol. Using electron and visible microscopy, we have shown that the mated pairs in stigmasterol remained adherent but prezygotic even after 12 hours incubation. Ergosterol rescued the cells and permitted zygote formation. Based on those experiments it was clear that membrane fusion was perturbed by sterol alterations. Continuing work with the renewal grant is focusing on membrane fusion in various normal cell biological processes. DTIC

COMPARATIVE TRANSDUCTION MECHANISMS OF VESTIBULAR OTOLITH HAIR CELLS Annual Report, 1 Jan. - 31 Dec. 1994
Richard A. Baird 31 Dec. 1994 90 p
(Contract NCC2-651)
(NASA-CR-197980; NAS 1.26:197980) Copyright Avail: CASI HC A05/MF A01

Hair cells in the bullfrog vestibular otolith organs regenerate following aminoglycoside ototoxicity. Hair cells in these organs are differentially sensitive to gentamicin, with saccular hair cells and hair cells in the utricular striola being damaged at lower gentamicin concentrations than hair cells in the utricular extrastriola. Regenerating hair cells in these organs have short hair bundles and can be classified into a number of phenotypes using the same morphological criteria used to identify their mature counterparts. Our studies suggest that some supporting cells can convert, or transdifferentiate,into hair cells without an intervening cell division. By stimulating these processes in humans, clinicians may be able to alleviate human deafness and peripheral vestibular disorders by regenerating and replacing lost hair cells. In vivo and in vitro studies were done on cell proliferation and hair cell regeneration. For individual titles, see N95-26728 through N95-26732.

REGIONAL DIFFERENCES IN LECTIN BINDING PATTERNS OF VESTIBULAR HAIR CELLS
Richard A. Baird, N. R. Schuff, and J. Bancroft *In its* Comparative Transduction Mechanisms of Vestibular Otolith Hair Cells 31 Dec. 1994 13 p Repr. from Hearing Research (New York, NY, Elsevier Science Publishers B.V.), v. 65, 1993 p 151-163 Sponsored by National Inst. of Deafness and Communicative Disorders, and Oregon Lions Sight and Hearing Foundation (For primary document see N95-26727 09-51)
(ISSN 0378-5955)
Avail: CASI HC A03/MF A01

Surface glycoconjugates of hair cells and supporting cells in the vestibular endorgans of the bullfrog were identified using biotinylated lectins with different carbohydrate specificities. Lectin binding in hair cells was consistent with the presence of glucose and mannose (CON A), galactose (RCA-I), N-acetylgalactosamine (VVA), but not fucose (UEA-I) residues. Hair cells in the bullfrog sacculus, unlike those in the utriculus and semicircular canals, did not stain for N-acetylglucosamine (WGA) or N-acetylgalactosamine (VVA). By contrast, WGA and, to a lesser extent, VVA, differentially stained utricular and semicircular canal hair cells, labeling hair cells located in peripheral, but not central, regions. In mammals, WGA uniformly labeled Type 1 hair cells while labeling, as in the bullfrog, Type 2 hair cells only in peripheral regions. These regional variations were retained after enzymatic digestion. We conclude that vestibular hair cells differ in their surface glycoconjugates and that differences in lectin binding patterns can be used to identify hair cell types and to infer the epithelial origin of isolated vestibular hair cells. HAIR CELL REGENERATION IN THE BULLFROG VESTIBULAR OTOLITH ORGANS FOLLOWING AMINOGLYCOSIDE TOXICITY
Richard A. Baird, M. A. Torres, and N. R. Schuff *In its* Comparative Transduction Mechanisms of Vestibular Otolith Hair Cells 31 Dec. 1994 11 p Repr. from Hearing Research (New York, NY, Elsevier Science Publishers B.V.), v. 65, 1993 p 164-174 Sponsored by National Inst. of Deafness and communicative Disorders, and Oregon Lions Sight and Hearing Foundation (For primary document see N95-26727 09-51)
Avail: CASI HC A01/MF A01

Adult bullfrogs were given single intraotic injections of the aminoglycoside antibiotic gentamicin sulfate and sacrificed at postinjection times ranging from 0.5 to 9 days. The saccular and utricular maculae of normal and injected animals were examined in wholemount and cross-section. Intraotic 200 (mu) M gentamicin concentrations resulted in the uniform destruction of the hair bundles and, at later times, the cell bodies of saccular hair cells. In the utriculus, striolar hair cells were selectively damaged while extrastriolar hair cells were relatively unaffected. Regenerating hair cells, identified in sectioned material by their small cell bodies and short, well-formed hair bundles, were seen in the saccular and utricular maculae as early as 24-48 h postinjection. Immature versions of mature hair cell types in both otolith organs were recognized by the presence of absence of a bulbed kinocilia and the relative lengths of their kinocilia and longest sterocilia. Utricular hair cell types with kinocilia longer than their longest stereocilia were observed at earlier times than hair cell types with shorter kinocilia. In the same sacculus, the hair bundles of gentamicin-treated animals, even at 9 days postinjection, were significantly smaller than those of normal animals. The hair bundles of utricular hair cells, on the other hand, reached full maturity within the same time period. Author

PERIPHERAL INNERVATION PATTERNS OF VESTIBULAR NERVE AFFERENTS IN THE BULLFROG UTRICULUS
Richard A. Baird and N. R. Schuff *In its* Comparative Transduction Mechanisms of Vestibular Otolith Hair Cells 31 Dec. 1994 20 p Repr. from The Journal of Comparative Neurology (New York, NY, Wiley-Liss, Inc.), v. 342, 1994 p 279-298 Sponsored by National Inst. of Deafness and Communicative Disorders, and Oregon Lions Sight and Hearing Foundation (For primary document see N95-26727 09-51)
Avail: CASI HC A03/MF A01

Vestibular nerve afferents innervating the bullfrog utriculus differ in their response dynamics and sensitivity to natural stimulation. They also supply hair cells that differ markedly in hair bundle morphology. To examine the peripheral innervation patterns of individual utricular afferents more closely, afferent fibers were labeled by the extracellular injection of horseradish peroxidase (HRP) into the vestibular nerve after sectioning the vestibular nerve medial to Scarpa's ganglion to allow the degeneration of sympathetic and efferent fibers. The peripheral arborizations of individual afferents were then correlated with the diameters of their parent axons, the regions of the macula they innervate, and the number and type of hair cells they supply. The utriculus is divided by the striola, a narrow zone of distinctive morphology, into media and lateral parts. Utricular afferents were classified as striolar or extrastriolar according to the epithelial entrance of their parent axons and the location of their terminal fields. In general, striolar afferents had thicker parent axons, fewer subepithelial bifurcations, larger terminal fields, and more synaptic endings than afferents in extrstriolar regions. Afferents in a juxtastriolar zone, immediately adjacent to the medial striola, had innervation patterns transitional between those in the striola and more peripheral parts of the medial extrastriola. moast afferents innervated only a single macular zone. The terminal fields of striolar afferents, with the notable exception of a few afferents with thin parent axons, were generally confined to one side of the striola. Hair cells in the bullfrog utriculus have perviously been classified into four types based on hair bundle morphology. Afferents in the extrastriolar and juxtastriolar zones largely or exclusively innervated Type B hair cells, the predominant hair cell type in the utricular macula. Striolar afferents supplied a mixture of four hair cell types, but largely contacted Type B and Type C hair cells, particularly on the outer rows of the medial striola. Afferents supplying more central striolar regions innervated fewer Type B and larger numbers of Type E and Type F hair cells. Striolar afferents with thin parent axons largely supplied Type E hair cells with bulbed kniocilia in the innermost striolar rows. Author

COMPARATIVE TRANSDUCTION MECHANISMS OF HAIR CELLS IN THE BULLFROG UTRICULUS. 1: RESPONSES TO INTRACELLULAR CURRENT

Richard A. Baird *In its* Comparative Transduction Mechanisms of Vestibular Otolith Hair Cells 31 Dec. 1994 19 p Repr. from Journal of Neurophysiology (Bethesda, MD, The American Physiological Society), v. 71, no. 2, Feb. 1994 p 666-683 Sponsored by National Inst. of Deafness and Communicative Disorders, and Oregon Lions Sight and Hearing Foundation (For primary document see N95-26727 09-51)
Avail: CASI HC A03/MF A01

Hair cells in the bullfrog sacculus are specifically adapted to sense small-amplitude, high-frequency linear accelerations. These hair cells display many properties that are undesirable or inappropriate for hair cells that must provide static gravity sensitivity. This study resulted in part due to an interest in seeing how the transduction mechanisms of hair cells in a gravity-sensing otolith endorgan would differ from those in the bullfrog sacculus. The bullfrog utriculus is an appropriate model for these studies, because its structure is representative of higher vertebrates in general and its function as a sensor of static gravity and dynamic linear acceleration is well known. Hair cells in the bullfrog utriculus, classifiable as Type 2 by cell body and synapse morphology, differ markedly in hair bundle morphology from those in the bullfrog sacculus. Moreover, the hair bundle morphologies of utricular hair cells, unlike those in the sacculus, differ in different membrane regions. Derived from text

COMPARATIVE TRANSDUCTION MECHANISMS OF HAIR CELLS IN THE BULLFROG UTICULUS. 2: SENSITIVITY AND RESPONSE DYNAMICS TO HAIR BUNDLE DISPLACEMENT

Richard A. Baird *In its* Comparative Transduction Mechanisms of Vestibular Otolith Hair Cells 31 Dec. 1994 21 p Repr. from Journal of Neurophysiology (Bethesda, MD, The American Physiological Society), v. 71, no. 2, Feb. 1994 p 685-705 Sponsored by National Inst. of Deafness and Communicative Disorders, and Oregon Lions Sight and Hearing Foundation (For primary document see N95-26727 09-51)
Avail: CASI HC A03/MF A01

The present study was motivated by an interest in seeing whether hair cell types in the bullfrog utriculus might differ in their voltage responses to hair bundle displacement. Particular interest was in assessing the contributions of two factors to the responses of utricular hair cells. First, interest in examining the effect of hair bundle morphology on the sensitivity of hair cells to natural stimulation was motivated by the observation that vestibular hair cells, unlike many auditory hair cells, are not free-standing but rather linked to an accessory cupular or otolithic membrane via the tip of their kinocilium. Interest also laid in examining the contribution, if any, of adaptation to the response properties of utricular hair cells. Hair cells in auditory and vibratory inner ear endorgans adapt to maintained displacements of their hair bundles, sharply limiting their low frequency sensitivity. This adaptation is mediated by a shift in the displacement-response curve (DRC) of the hair cell along the displacement axis. Observations suggest that the adaptation process occurs within the hair bundle and precedes mechanoelectric transduction. Recent observations of time-dependent changes in hair bundle stiffness are consistent with this conclusion. Adaptation would be expected to be most useful in inner ear endorgans in which hair cells are subject to large static displacements that could potentially saturate their instantaneous response and compromise their sensitivity to high frequency stimulation. The adaptation process also permits hair cells to maintain their sensory hair bundle in the most sensitive portion of their DRC. In vestibular otolith organs in which static sensitivity is desirable, any adaptation process in the hair cells may be undesirable. The rate and extent of the decline of the voltage responses was measured of utricular hair cells to step and sinusoidal hair bundle displacements. Then for similar resting potentials and response amplitudes, the voltage responses of individual hair cells were compared to both hair bundle displacement and intracellular current. A MODEL OF THE NEURAL BASIS OF THE RAT'S SENSE OF DIRECTION

William E. Skaggs, James J. Knierim, and Hemant S. Kudrimoti 1994 8 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289678) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

In the last decade the outlines of the neural structures subserving the sense of direction have begun to emerge. Several investigations have shed light on the effects of vestibular input and visual input on the head direction representation. In this paper, a model is formulated of the neural mechanisms underlying the head direction system. The model is built out of simple ingredients, depending on nothing more complicated than connectional specificity, attractor dynamics, Hebbian learning and sigmoidal nonlinearities, but it behaves in a sophisticated way and is consistent with most of the observed properties of real head direction cells. In addition it makes a number of predictions that ought to be testable by reasonably straightforward experiments. DTIC

DIAGNOSTIC ANTIGENS OF LEISHMANIA Final Report

Steven G. Reed 31 Jan. 1994 20 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAMD17-92-C-2082)
(AD-A288805) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

We report herein the cloning, expression, and seroreactivity of three Leishmania tropica antigens. By ELISA analysis, the majority of confirmed and suspected viscerotropic leishmaniasis patients had significantly higher levels of specific antibody against two of the three recombinant antigens and the repeat portion of one of the antigens, named Lt-Ir, when compared to sera from normal controls. The molecular characterization of these two antigens demonstrated that these are adjacent portions of the same gene and that the repeat portion contains one of the immunodominant epitopes. In addition, this gene was shown to be conserved in all strains of L. tropica parasites recovered from Gulf War participants. The gene does not appear to be highly conserved among all species of Leishmania. Collectively, the data indicate the potential for these antigens to assist in the diagnosis of individuals with viscerotropic leishmamasis. DTIC

HIPPOCAMPAL PLACE FIELDS, THE INTERNAL COMPASS, AND THE LEARNING OF LANDMARK STABILITY

James J. Knierim, Hemant S. Kudrimoti, and Bruce L. McNaughton 16 May 1994 48 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract N00014-90-J-1869)
(AD-A289406) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Previous studies have shown that hippocampal place fields are controlled by the salient sensory cues in the environment, in that rotation of the cues causes an equal rotation of the place fields. We trained rats to forage for food pellets in a gray cylinder with a single salient directional cue, a white card covering 900 of the wall. Half of the rats were disoriented before being placed in the cylinder, in order to disrupt their internal sense of direction. The other half were not disoriented before being placed in the cylinder; for these rats, there was presumably a consistent relationship between the cue card and their internal direction sense. We subsequently recorded hippocampal place cells and thalamic head direction cells from both groups of rats as they moved in the cylinder, between some sessions the cylinder and cue card were rotated to a new direction. All rats were disoriented before recording. Under these conditions, the cue card had much weaker control over the place fields and head direction cells in the rats that had been disoriented during training than in the rats that had not been disoriented. For the former group, the place fields often rotated relative to the cue card or completely changed their firing properties between sessions. In all recording sessions, the head direction cells and place cells were strongly coupled. It appears that the strength of cue control over place cells and head direction cells depends on the rat's learned perception of the stability of the cues. DTIC

THE ELECTRICAL BEHAVIOUR OF AN EXCITABLE CELL AT DIFFERENT CONDITIONS
M. El-Sayed and A. M. Mohammed Aug. 1994 23 p
(DE95-607911; IC-94/232) Avail: CASI HC A03/MF A01

The Hodgkin-Huxley, H-H, model has been modified, in this work, to study the electrical behaviour of an excitable cell due to changes in the permeability of K and Na ions (g(sub k) and g(sub Na)), the simultaneous stochastic variations of g(sub k) and g(sub Na), the current stimulus (Jstim) and the non-inactivation of Na-channel (NI - NaC). The amplitude and duration of the generated action potential (AP) was found to increase as g(sub k) increases, with the appearance of repetitive AP spikes in the range of 21.5 (greater than or equal to) g(sub k) (greater than or equal to) 3.5 while the K- and Na-currents (J(sub k) and J(sub Na)) showed a pronounced decrease. On the other hand, the increase of g(sub Na) was accompanied by an increase in AP amplitudes and durations and also in J(sub k) and J(sub Na) with the appearance of a repetitive AP at 1400 (greater than or equal to) g(sub Na) (greater than or equal to) 189 ms/sq cm whose frequency increases with the increase of g(sub Na). Moreover, the stochastic variations in g(sub k) and g(sub Na) could generate a repetitive AP whose frequency could be changed either by changing the values of g(sub k) or g(sub Na) or both, and may represent an information carried by the sensory cells for example. The electrical behaviour of the simulated cell can also be affected by Jstim at different values of g(sub k) except at the range of 21.5 (greater than or equal to) g(sub k) (greater than or equal to) 3.5 ms/sq cm and also depended on NI - NaC fraction. AUTOMATED INTEGRATION OF GENOMIC PHYSICAL MAPPING DATA VIA PARALLEL SIMULATED ANNEALING
T. Slezak Jun. 1994 19 p Presented at the 3d International Conference on Bioinformatics and Genome Research, Tallahassee, FL, 1-4 Jun. 1994
(Contract W-7405-eng-48)
(DE95-008057; UCRL-JC-117666; CONF-9406311-1) Avail: CASI HC A03/MF A01

The Human Genome Center at the Lawrence Livermore National Laboratory (LLNL) is nearing closure on a high-resolution physical map of human chromosome 19. We have build automated tools to assemble 15,000 fingerprinted cosmid clones into 800 contigs with minimal spanning paths identified. These islands are being ordered, oriented, and spanned by a variety of other techniques including: Fluorescence Insitu Hybridization (FISH) at 3 levels of resolution, ECO restriction fragment mapping across all contigs, and a multitude of different hybridization and PCR techniques to link cosmid, YAC, AC, PAC, and PI clones. The FISH data provide us with partial order and distance data as well as orientation. We made the observation that map builders need a much rougher presentation of data than do map readers; the former wish to see raw data since these can expose errors or interesting biology. We further noted that by ignoring our length and distance data we could simplify our problem into one that could be readily attacked with optimization techniques. The data integration problem could then be seen as an M x N ordering of our N cosmid clones which 'intersect' M larger objects by defining ' intersection' to mean either contig/map membership or hybridization results. Clearly, the goal of making an integrated map is now to rearrange the N cosmid clone 'columns' such that the number of gaps on the object 'rows' are minimized. Our FISH partially-ordered cosmid clones provide us with a set of constraints that cannot be violated by the rearrangement process. We solved the optimization problem via simulated annealing performed on a network of 40+ Unix machines in parallel, using a server/client model built on explicit socket calls. For current maps we can create a map in about 4 hours on the parallel net versus 4+ days on a single workstation. Our biologists are now using this software on a daily basis to guide their efforts toward final closure. DOE

ENERGY TRANSFER IN REAL AND ARTIFICIAL PHOTOSYNTHETIC SYSTEMS
J. C. Hindman, J. E. Hunt, and J. J. Katz 1995 23 p
(Contract W-31-109-eng-38)
(DE95-005824; ANL/CHM/PP-80864) Avail: CASI HC A03/MF A01

Fluorescence emission from the photosynthetic organisms Tribonema aequale, Anacystis nidulau, and Chlorella vulgais and from some chlorophyll model systems have been recorded as a function of excitation wavelength and temperature. Considerable similarity was observed in the effects of excitation wavelength and temperature on the fluorescence from intact photosynthetic organisms and the model systems. The parallelism in behavior suggest that self-assembly processes may occur in both the in vivo and in vitro systems that give rise to chlorophyll species at low temperature that may differ significantly from those present at ambient temperatures. MUTAGENESIS IN HUMAN CELLS WITH ACCELERATED H AND Fe IONS Final Report, May 1991 - Apr. 1994
Amy Kronenberg Apr. 1994 12 p
(NASA Order T-9309-R)
(NASA-CR-198599; NAS 1.26:198599) Avail: CASI HC A03/MF A01

The overall goals of this research were to determine the risks of mutation induction and the spectra of mutations induced by energetic protons and iron ions at two loci in human lymphoid cells. During the three year grant period the research has focused in three major areas: (1) the acquisition of sufficient statistics for human TK6 cell mutation experiments using Fe ions (400 MeV/amu), Fe ions (600 MeV/amu) and protons (250 MeV/amu); (2) collection of thymidine kinase- deficient (tk) mutants or hypoxanthine phosphoribosyltransferase deficient (hprt) mutants induced by either Fe 400 MeV/amu, Fe 600 MeV/amu, or H 250 MeV/amu for subsequent molecular analysis; and (3) molecular characterization of mutants isolated after exposure to Fe ions (600 MeV/amu). As a result of the shutdown of the BEVALAC heavy ion accelerator in December 1992, efforts were rearranged somewhat in time to complete our dose-response studies and to complete mutant collections in particular for the Fe ion beams prior to the shutdown. These goals have been achieved. A major effort was placed on collection, re-screening, and archiving of 3 different series of mutants for the various particle beam exposures: tk-ng mutants, tk-sg mutants, and hprt-deficient mutants. Where possible, groups of mutants were isolated for several particle fluences. Comparative analysis of mutation spectra has occured with characterization of the mutation spectrum for hprt-deficient mutants obtained after exposure of TK6 cells to Fe ions (600 MeV/amu) and a series of spontaneous mutants. THIRD INTERNATIONAL CONGRESS OF PLANT MOLECULAR BIOLOGY: MOLECULAR BIOLOGY OF PLANT GROWTH AND DEVELOPMENT

Richard B. Hallick, ed. 1995 421 p Congress held in Tucson, AZ, 6-11 Oct. 1991
(Contract DE-FG09-90ER-20012)
(DE95-006482; CONF-9110552-Absts) Avail: CASI HC A18/MF A04

The Congress was held 6-11 Oct. 1991 in Tucson with approximately 3000 scientists attending and over 300 oral presentations and 1800 posters. Plant molecular biology is one of the most rapidly developing areas of the biological sciences. Recent advances in the ability to isolate genes, to study their expression, and to create transgenic plants have had a major impact on our understanding of the many fundamental plant processes. In addition, new approaches have been created to improve plants for agricultural purposes. This is a book of presentation and posters from the conference. DOE

DEVELOPMENT AND APPLICATION OF LOW-TEMPERATURE AFM Final Report, 1 Nov. 1991 - 31 Oct. 1994

Jie Yang and Zhifeng Shao 30 Jan. 1995 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-92-G-0002)
(AD-A291704; ARO-29194.9-LS) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

With the support from the US Army Research Office, we have established the basis of using state-of-the-art atomic force microscope (AFM) to image biological specimens at sub-nm resolution at cryogenic temperatures under ambient pressure. Our instrumentation demonstrated convincingly that a contamination environment can be obtained as we proposed originally, and the performance of our prototype AFM at cryogenic temperatures was at least comparable to, if not better than, any atomic force microscope available today. We have also developed various methods to facilitate atomic force microscopy of biological specimens at room temperature. Modification of the Kleinschmidt methods enabled us to image DNA specimens in air at a resolution of 4-6 nm. Reliable preparation of supported bilayers enabled us to study the structure of lipid bilayers in situ, leading to the elucidation of interesting phenomena which are impossible to reveal by other available methods, and the imaging of membrane proteins in physiological conditions at a resolution of 1 nm. We also developed methods to image soluble proteins in solution at a resolution of 1 nm. These suggest strongly the usefulness of AFM in biology that it can be used to solve problems which are difficult to tackle with other methods. DTIC

INTERNATIONAL JOURNAL OF QUANTUM CHEMISTRY Final Report, 1 Jan. - 31 Dec. 1994

Rodney J. Bartlett Feb. 1995 253 p Presented at the 21st Quantum Biology Symposium, Ponte Verda Beach, FL, 12-19 Feb. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAH04-94-G-0015)
(AD-A291633; ARO-32557.1-PH-CF) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The 34th Annual Sanibel Symposium, organized by the faculty and staff of the Quantum Theory Project of the University of Florida, was held on February 12-19, 1994, at the Marriott, Sawgrass Resort, Ponte Vedra Beach, Florida. Over 300 participants gathered for 8 days of lectures and informal discussions. The format of the symposium adopted for the past few years was followed again this year with a compact 8-day schedule with an integrated program of quantum biology, quantum chemistry, and condensed matter physics. The topics of the sessions covered by these proceedings include Quantum Chemistry of Biological Molecules, Spectroscopic Signatures of Biological Molecules, Protein Folding, and Photosynthesis. DTIC

DEVELOPMENT OF AN ACUITY-BASED NURSE STAFFING SYSTEM FOR THE POST ANESTHESIA CARE UNIT Final Report, 1992 - 1993

Julie K. Zadinsky Nov. 1994 143 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288831; HR95-001) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The purposes of the study were (1) to provide an acuity-based method of determining nurse staffing needs for post anesthesia care units (PACU's) in the Army Medical Department (AMEDD) and (2) to provide a method of analyzing PACU workload variation. This method of determining staffing needs and analyzing workload variation is known as the Post Anesthesia Care Staffing System (PACS). Data were collected using (1) the PACU acuity worksheet at six study sites for a 16-week period, (2) records of nursing hours worked when the acuity information was being collected, and (3) a survey of PACU characteristics sent to 39 Army PACU's in the U.S. Army Health Services Command (HSC, now the U.S. Army Medical Command or MEDCOM). The strong positive correlation (r greater than .90) between daily direct nursing care hours and patient volume supported the development of a general regression model that was used to estimate daily direct nursing care hours from patient volume information. MECHANISMS OF HYPERTENSION AFTER CROSS-LINKED HEMOGLOBIN BLOOD-SUBSTITUTE TRANSFUSION Midterm Report

Michael J. Joyner 1 Dec. 1994 19 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAMD17-93-C-3116)
(AD-A289558) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The USAMRDC has developed a 'blood substitute' containing cross-linked human hemoglobin (XL-Hgb) in a physiologic saline solution. In animal models, this material can sustain life in the absence of red blood cells and is effective in resuscitating experimental animals from hypovolemic hemorrhagic shock. A persistent side-effect of XL-Hgb administration in animals has been marked arterial and pulmonary hypertension. The mechanism of this hypertension is unknown, but it is hypothesized that the XL-Hgb scavenges the endogenous vasodilating substance nitric oxide (NO). In experiments to date, our group has demonstrated that XL-Hgb administration (1) appears to blunt NO-mediated vasodilation in isolated blood vessels; (2) disrupts the normal metabolism of catecholamines from the adrenal medulla and sympathetic nerve endings;

(3) blunts NO-mediated vasodilation in vivo; and (4) causes acute volume expansion and hypertension without the normally observed diuresis and natriuresis in vivo. Studies to date generally confirm the hypothesis that XL-Hgb interferes with NO function in isolated tissues and whole animals. Additionally, other poorly understood physiologic mechanisms may also contribute to the hypertension. DTIC

AEROSPACE MEDICINE Occupational Survey Report

Todd W. Kustra, Harold Huguley, III, and Becky Hernandez Nov. 1994 69 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289691; AFPT-90-901-961) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report summarizes the occupational survey results of the Aerospace Medicine Physician utilization field (935X) and the Aerospace Medicine career field (901X0). USAFSAM/ED requested the survey to analyze the effectiveness of the current training program for Aerospace Medicine utilization field (AFSC 93 5X). The analysis incorporates an assessment of the tasks trained in the Aerospace Medicine Primary course and the Aeromedical Specialist course; there is an evaluation of tasks listed in the Course Training Standard (CTS), Specialty Training Standard (STS), and the Career Development Course (CDC); and a comparison of tasks required versus actual tasks performed by incumbents. In addition, several other issues will be analyzed, such as the emergency skills needed for Squadron Medical Element personnel versus those needed for non-Squadron Medical Element personnel, the amount of time spent on patient care versus time spent performing administrative duties, and the scope of job satisfaction for both officers and enlisted personnel. BASIC MECHANISMS AND IMPLICATIONS OF NON-PHOTIC ENTRAINMENT OF CIRCADIAN RHYTHMICITY Annual Report, 1 Sep. 1993 - 31 Aug. 1994

Eve VanCauter 31 Aug. 1994 7 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(Contract F49620-92-J-0347)

(AD-A288433; AFOSR-94-0752TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The overall objectives of AFOSR-sponsored studies in Dr Van Cauter's laboratory are to delineate the synchronizing effects of physical exercise and exposure to darkness on the human circadian system and to test the hypothesis that additive effects of adequately timed exposure to pulses of bright light, darkness and exercise may result in large, immediate phase-shifts of human rhythms. Mr. Buxton performed a series of studies related to the first specific aim of the project, namely, to define the role of exercise intensity and duration in causing phase-shifts. The major rationale for examining the role of exercise intensity and duration in causing phase-shifts is to determine whether exercise sessions that can more readily be achieved in real life conditions than a 3-hour period of arm and leg exercise (which was the exercise period used in our previous studies), will have similar zeitgeber potency. Additionally, the use of a shorter duration, higher intensity stimulus would result in more clear-cut neuroendocrine correlates correlates of exercise and may provide important insights regarding the phase-dependence of exercise-induced neuroendocrine activation. A MODEL OF BUBBLE EVOLUTION DURING DECOMPRESSION BASED ON A MONTE CARLO SIMULATION OF INERT GAS DIFFUSION Technical Report, Jun. 1992 - 1993

R. Ball, J. Himm, L. D. Homer, and E. D. Thalmann Aug. 1994 139 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(DA Proj. MM3-3-P-30)

(AD-A289400; NMRI-94-36) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Previously, a Monte Carlo simulation of inert gas diffusion in a capillary bed had been developed at this laboratory to explore the effect of tissue heterogeneity and microvascular architecture on gas exchange under normobaric conditions. Because we needed a method of looking at gas phase dynamics during decompression in this environment, the Monte Carlo method was extended to simulate bubble growth and dissolution during decompression. The essence of our approach involves the placement of inert gas particles in a bubble-liquid module and simulating diffusion with random displacements within the module for a short, fixed time period. At the end of the time period the distribution of the particles is used to calculate the number of moles of gas inside the bubble. The new bubble volume is then calculated from the ideal gas law. We developed methods to speed up the simulation by computing distributions of displacements following many random steps so that the simulation of many steps might be made with a simple calculation. In addition, we can calculate the amount of time a particle will stay inside the bubble based on the solubility of the inert gas. We demonstrate that a bubble evolves to the expected equilibrium size and the time course of the evolution compares favorably with that predicted by a partial differential equation model. A Monte Carlo approach is successful in simulating bubble evolution during decompression and is potentially suitable for studying the influence of tissue micro-architecture on gas phase dynamics. NON-INVASIVE METHOD AND APPARATUS FOR MONITORING INTRACRANIAL PRESSURE AND PRESSURE VOLUME INDEX IN HUMANS Patent Application

John H. Cantrell, inventor (to NASA) and William T. Yost, inventor (to NASA) 24 Aug. 1994 30 p

(NASA-Case-LAR-13894-1; NAS 1.71:LAR-13894-1; US-Patent-Appl-SN-297474) Avail: CASI HC A03/MF A01

Non-invasive measuring devices responsive to changes in a patient's intracranial pressure (ICP) can be accurately calibrated for monitoring purposes by providing known changes in ICP by non-invasive methods, such as placing the patient on a tilting bed and calculating a change in ICP from the tilt angle and the length of the patient's cerebrospinal column, or by placing a pressurized skull cap on the patient and measuring the inflation pressure. Absolute values for the patient's pressure-volume index (PVI) and the steady state ICP can then be determined by inducing two known changes in the volume of cerebrospinal fluid while recording the corresponding changes in ICP by means of the calibrated measuring device. The two pairs of data for pressure change and volume change are entered into an equation developed from an equation describing the relationship between ICP and cerebrospinal fluid volume. PVI and steady state ICP are then determined by solving the equation. Methods for inducing known changes in cerebrospinal fluid volume are described. NASA

IMAGE PERCEPTION WAVELET SIMULATION AND ENHANCEMENT FOR THE VISUALLY IMPAIRED M.S. Thesis

Lemuel R. Myers, Jr. Dec. 1994 96 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(AD-A289303; AFIT/GEO/ENG/94D-03) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research delves into the area of image enhancement for the visually impaired. Binocular macular degeneration a visual impairment, affects many Americans; since this condition could not be corrected with conventional glasses the literature suggested using an enhancement system which used a pre-emphasis algorithm to enhance the input image for output to the observer. The work of Dr. Eli Peli, a pioneer in the field of image enhancement, is examined and reproduced. Since his work concentrated mainly on frequency analysis of images, the bulk of this research involves using discrete wavelet analysis to augment that work. A biorthogonal wavelet set is used to enhance images. That same wavelet set is used to provide a simulation of a person's perception of an image based upon that person contrast sensitivity function. The wavelet enhancement follows Dr. Peli's method of enhancement using a modified pre-emphasis filter. The wavelet enhancement results are similar to that technique, with the most notable difference being that wavelet enhancements tend to accentuate the horizontal and vertical details of the image more than the spatial frequency concentric filter techniques outlined by Peli and others. The perception simulations use wavelet analysis and are based on the work accomplished by Peli concerning 'local band-limited contrast,' with the frequency analysis of that work giving way to a wavelet analysis;

the results here are significantly different than those result seen in the Peli simulation. DTIC

EXPERIMENTAL DEFINITION FOR IMPLANTATION OF THE AFIT CORTICAL MULTIELECTRODE ARRAY M.S. Thesis

Adam G. Spenik Dec. 1994 94 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289216; AFIT/GE/ENG/94D-27) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

A two-dimensional multiplexed array of 256 electrodes (16 x 16) has been fabricated using conventional CMOS fabrication techniques. The size and spacing of the electrodes (160 x 160 micrometer squares with center-to-center spacing of 250 micrometer) approximate that of the cortical columns. The device is mounted on a small biocompatible package and a protocol to implant this package on the visual cortex of a ferret and a Rhesus monkey was developed and approved. An instrumentation setup to record the data from the device is described as well as the methods used to demultiplex the data. Testing of the device in a simulated cortical environment indicates that the device is capable of recording signals with amplitudes as low as 20 micro volts. This capability is significant as the level of the cortical signal ranges from 20-500 micro volts. An experiment is envisioned in which the primary and secondary visual areas of a mammal are monitored simultaneously in an attempt to gather data while the brain is actually performing perception. This type of study will provide insight to the nature of the organization of the cortico-cortical connectivity matrix and its relation to the function of the cortical column system. DTIC

CHARACTERIZATION AND REDESIGN OF THE AFIT MULTIELECTRODE ARRAY M.S. Thesis

Richard G. Darenberg Dec. 1994 120 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A289295; AFIT/GE/ENG/94D-03) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Since 1978, faculty and graduate students from the Air Force Institute of Technology (AFIT) have been working on an implantable circuit array that can record visual signals from the brain or stimulate the brain. In the current design the circuit is a 16 x 16 array of pads, each pad being 160 x 160 micrometers with 250 micrometers spacing with an 'L' shaped reference pad used as a ground reference. The array is multiplexed so that only one I/O line is required to access all 256 pads. This research was twofold: first to analyze the existing circuit and identify sources for noise and then to redesign the circuit with the intent of reducing noise and power consumption. As a result of the research, a new 16 x 17 array has been developed. The new design incorporates new demultiplexing and synchronizing circuitry. The new circuitry exhibits lower noise and consumes much less power. The 'L' shaped reference pad has been removed-instead each pad and the pad to its right are sampled concurrent1y-one as the sample and one as a reference. DTIC

MATRIX KERNELS FOR MEG AND EEG SOURCE LOCALIZATION AND IMAGING

J. C. Mosher, P. S. Lewis, and R. M. Leahy (University of Southern California, Los Angeles, CA.) 1994 4 p Presented at the IEEE Conference on Acoustics, Speech and Signal Processing, Detroit, MI, 8-12 May 1995
(Contract W-7405-eng-36)
(DE95-005238; LA-UR-94-4387; CONF-9505158-2) Avail: CASI HC A01/MF A01

The most widely used model for electroencephalography (EEG) and magnetoencephalography (MEG) assumes a quasi-static approximation of Maxwell's equations and a piecewise homogeneous conductor model. Both models contain an incremental field element that linearly relates an incremental source element (current dipole) to the field or voltage at a distant point. The explicit form of the field element is dependent on the head modeling assumptions and sensor configuration. Proper characterization of this incremental element is crucial to the inverse problem. The field element can be partitioned into the product of a vector dependent on sensor characteristics and a matrix kernel dependent only on head modeling assumptions. We present here the matrix kernels for the general boundary element model (BEM) and for MEG spherical models. We show how these kernels are easily interchanged in a linear algebraic framework that includes sensor specifics such as orientation and gradiometer configuration. We then describe how this kernel is easily applied to 'gain' or 'transfer' matrices used in multiple dipole and source imaging models. DOE

AN INTRODUCTORY GUIDE TO UNCERTAINTY ANALYSIS IN ENVIRONMENTAL AND HEALTH RISK ASSESSMENT. ENVIRONMENTAL RESTORATION PROGRAM

J. S. Hammonds, F. O. Hoffman, and S. M. Bartell Dec. 1994 39 p
(Contract DE-AC05-84OR-21400)
(DE95-008097; ES/ER/TM-35/R1) Avail: CASI HC A03/MF A01

This report presents guidelines for evaluating uncertainty in mathematical equations and computer models applied to assess human health and environmental risk. Uncertainty analyses involve the propagation of uncertainty in model parameters and model structure to obtain confidence statements for the estimate of risk and identify the model components of dominant importance. Uncertainty analyses are required when there is no a priori knowledge about uncertainty in the risk estimate and when there is a chance that the failure to assess uncertainty may affect the selection of wrong options for risk reduction. Uncertainty analyses are effective when they are conducted in an iterative mode. When the uncertainty in the risk estimate is intolerable for decision-making, additional data are acquired for the dominant model components that contribute most to uncertainty. This process is repeated until the level of residual uncertainty can be tolerated. A analytical and numerical methods for error propagation are presented along with methods for identifying the most important contributors to uncertainty. Monte Carlo simulation with either Simple Random Sampling (SRS) or Latin Hypercube Sampling (LHS) is proposed as the most robust method for propagating uncertainty through either simple or complex models. A distinction is made between simulating a stochastically varying assessment endpoint (i.e., the distribution of individual risks in an exposed population) and quantifying uncertainty due to lack of knowledge about a fixed but unknown quantity (e.g., a specific individual, the maximally exposed individual, or the mean, median, or 95%-tile of the distribution of exposed individuals). Emphasis is placed on the need for subjective judgement to quantify uncertainty when relevant data are absent or incomplete. DOE

A previous study of the heart rate (HR) response to positive pressure breathing (PPB), anxiety and hypoxia during rapid decompression (RD) revealed a consistent pattern in the beat-to-beat or interbeat interval variability of HR, known in the literature as heart rate variability (HRV). One method of analyzing HRV is a noninvasive measure of the respiratory-cardiac neural reflex known as vagal tone monitoring. This method is based on the amplitude of respiratory sinus arrhythmia (RSA) as a manifestation of vagal cardioinhibitory influence on the heart. The RD/HR data were interpreted by two HRV analysis methods, vagal tone monitoring (VTM) and a method developed in-house based on maximum entropy method (MEM) (spectral analysis), as a means of studying the heart rate regulating mechanisms during RD. A significant drop in vagal tone in both HRV measures was shown during the PPB and hypoxia profiles. Conflicting results regarding the anxiety profile during RD leave room for questions as to the use of these HRV measures as a tool for assessing anxiety or emotional stress. However, these measures only examined a subset of the HRV frequency spectrum (the respiratory frequency range) which provides information only on the parasympathetic autonomic contributions. Investigation of other frequency bands may provide more complete data on the autonomic regulation of the cardiovascular system. DTIC
